

Sudan Household Health Survey 2010

NATIONAL REPORT

November 2012

Preface

The Sudan Household Health Survey - Second Round (SHHS2) was carried out during the period March to May 2010 by the Federal Ministry of Health (FMOH) and the Central Bureau of Statistics (CBS) of the Republic of Sudan. The SHHS2 was carried out in collaboration with several ministries and institutions of the Government of Sudan such as the Ministry of International Cooperation, Ministry of Education, Ministry of Welfare and Social Security National Population Council, National Council for Child Welfare (NCCW) and National Water Corporation as well as regional and international organisations such as the United Nations Children's Fund (UNICEF), the United Nations Population Fund (UNFPA), the World Health Organization (WHO), the United Nations Development Programme (UNDP), the World Food Programme (WFP), the UNAIDS, the Pan Arab Project for Family Health (PAPFAM), the United States Agency for International Development (USAID) and the Japan International Cooperation Agency (JICA).

The methodology and content of SHHS2 was based on the Multiple Indicator Cluster Survey (MICS) and Pan Arab Project for Family Health (PAPFAM). The SHHS2 was conducted as part of the fourth global round of MICS. The SHHS2 report provides up-to-date information on the situation of children and women in Sudan and on key indicators that allow the country to monitor progress towards some of the national development goals, targets, the MDGs and other internationally agreed upon commitments.

Summary Table of Findings Sudan Household Health Survey (SHHS2) and Millennium Development Goals (MDG) Indicators, Sudan, 2010				
Topic	SHHS2 indicator number	MDG indicator number	SHHS2 Indicator	Value/1000 live birth
CHILD MORTALITY				
Child mortality	1.1		Neonatal mortality rate	34
	1.2		Post-neonatal mortality rate	26
	1.3	4.2	Infant mortality rate	60
	1.4		Child mortality rate	24
	1.5	4.1	Under-five mortality rate	83
NUTRITION				
Nutritional status				Percent
	2.1a 2.1b	1.8	Underweight prevalence Moderate and Severe (- 2 SD) Severe (- 3 SD)	32 13
	2.2a 2.2b		Stunting prevalence Moderate and Severe (- 2 SD) Severe (- 3 SD)	35 16
	2.3a 2.3b		Wasting prevalence Moderate and Severe (- 2 SD) Severe (- 3 SD)	16 05
Breastfeeding and infant feeding	2.4		Children ever breastfed	99
	2.5		Early initiation of breastfeeding	73
	2.6		Exclusive breastfeeding under 6 months	41
	2.7		Continued breastfeeding at 1 year	88
	2.8		Continued breastfeeding at 2 years	40
	2.9		Pre dominant breastfeeding under 6 months	80
	2.10		Duration of breastfeeding	19
	2.11		Bottle feeding	05
	2.12		Introduction of solid, semi-solid or soft foods	51
	2.13		Minimum meal frequency	30
2.14		Age-appropriate breastfeeding	49	
2.15		Milk feeding frequency for non-breastfed children	56	
Salt iodization	2.16		Iodized salt consumption	10
Vitamin A	2.17		Vitamin A supplementation (children under age 5)	61
CHILD HEALTH				Value
Vaccinations	3.1		Tuberculosis immunization coverage	75
	3.2		Polio immunization coverage	62
	3.3		Immunization coverage for diphtheria, pertussis and tetanus (DPT)	58
	3.4	4.3	Measles immunization coverage	62
	3.5		Hepatitis B immunization coverage	
Tetanus toxoid	3.7		Neonatal tetanus protection	55

Summary Table of Findings				
Sudan Household Health Survey (SHHS2) and Millennium Development Goals (MDG) Indicators, Sudan, 2010				
Topic	SHHS2 indicator number	MDG indicator number	SHHS2 Indicator	Value/1000 live birth
Care of illness	3.8		Oral rehydration therapy with continued feeding	12
	3.9		Care seeking for suspected pneumonia	55
	3.10		Antibiotic treatment of suspected pneumonia	66
Solid fuel use	3.11		Solid fuels	63
Malaria	3.16		Malaria diagnostics usage	57
	3.17		Anti-malarial treatment of children under 5 the same or next day	43
	3.18	6.8	Anti-malarial treatment of children under age 5	65
WATER AND SANITATION				
Water and sanitation	4.1	7.8	Use of improved drinking water sources	61
	4.2		Water treatment	14
	4.3	7.9	Use of improved sanitation facilities	27
	4.4		Safe disposal of child's faeces	46
REPRODUCTIVE HEALTH				
Contraception and unmet need	5.2		Early childbearing	14
	5.3	5.3	Contraceptive prevalence rate	9
	5.4	5.6	Unmet need	26
Maternal and new born health	5.5a	5.5	Antenatal care coverage	74
	5.5b		At least once by skilled personnel	47
	5.6		Content of antenatal care	52
	5.7	5.2	Skilled attendant at delivery	73
	5.8		Institutional deliveries	21
	5.9		Caesarean section	7

EDUCATION				Percent
Literacy	6.1	2.3	Literacy rate among young women 15-24 years	45
Early childhood care and education	6.2		School readiness (children age 4-5 years)	45
	6.3		Net intake rate in primary education	46
Primary school participation	6.4	2.1	Primary school net attendance ratio (adjusted)	72.1
	6.5		Secondary school net attendance ratio (adjusted)	32
	6.6	2.2	Children reaching last grade of primary education (grade VIII)	82
	6.7		Primary completion rate	63
	6.8		Transition rate to secondary school	78
	6.9		Gender parity index (primary school)	0.94
	6.10		Gender parity index (secondary school)	1.08
CHILD PROTECTION				
Birth registration	7.1		Birth registration	59
Early marriage and polygyny	7.6		Marriage before age 15	96.
	7.7		Marriage before age 18	38
	7.8		Young women age 15-19 currently married or in union	24
	7.9		Polygyny	20
Female genital mutilation/cutting	7.11		Approval for female genital mutilation/cutting (FGM/C)	48
	7.12		Prevalence of female genital mutilation/cutting (FGM/C) among women	66
	7.13		Prevalence of female genital mutilation/cutting (FGM/C) among girls	
Domestic violence	7.14		Attitudes towards domestic violence	47
Orphaned children	7.15		Children's living arrangements (not living with a biological parent)	4
	7.16		Prevalence of children with at least one parent dead	6
	7.17	6.4	School attendance of orphans	79
	7.18	6.4	School attendance of non-orphans	82
HIV/AIDS knowledge and attitude				
	8.1		Comprehensive knowledge of about HIV prevention among women age 15-49 years	19
	8.2		Knowledge of mother-to-child transmission of HIV among women age 15-49 years	60
	8.3		Women age 15-49 years who express an accepting attitudes towards people living with HIV/AIDS	8
	8.4	9.1	Women who know where to be tested for HIV	14
	8.5		Women age 15-49 years who have been tested for AIDS virus and been told of the results of the test	1

Acknowledgement

The Federal Ministry of Health (FMOH) and the Central Bureau of Statistics (CBS) of the Republic of Sudan would like to acknowledge the support of many individuals, ministries and institutions of the Government of Sudan and regional and international agencies/organisations which contributed to the successful completion of the Sudan Household Health Survey – Second Round, 2010 (SHHS2).

On behalf of the SHHS2 management team, I would like to place on record our deep appreciation and to the chairpersons and members of the Steering Committee and technical working group, head and members of the national-level coordination (executive) body and leader and members of the state-level teams who had played an important role in the completion of the survey.

Special appreciation is due to the ministries and institutions of the Government of Sudan such as the Ministry of International Cooperation, Ministry of Education, Ministry of Social Welfare and Women and Child Affairs, National Population Council, National Council for Child Welfare (NCCW) and National Water Corporation for their support to the various tasks relating to the planning and implementation of the SHHS2.

In particular, the Federal Ministry of Health (FMOH) and the Central Bureau of Statistics (CBS) would like to acknowledge the financial and technical support provided by the United Nations Children's Fund (UNICEF), the United Nations Population Fund (UNFPA), the World Health Organization (WHO), the United Nations Development Programme (UNDP), the World Food Programme (WFP), the UNAIDS, the United States Agency for International Development (USAID) and the Japan International Cooperation Agency (JICA) and the key role played by them in the planning and implementation of various tasks relating to the survey. The technical assistance provided by the Pan Arab Project for Family Health (PAPFAM) is gratefully acknowledged. Special thanks are extended to experts from UNICEF headquarters and UNICEF Middle East and North Africa Regional Office who provided technical support to facilitate effective planning and implementation of the survey, including the preparation of survey tools and data analysis.

Our sincere gratitude goes to all the staff, especially those at the States and locality levels who participated in the SHHS Survey for their strong support from the inception to the completion of the survey. Special thanks to Dr. Igbal A. Bashir, Survey Executive Director, FMOH and Mr. Amin Daoud-Data Processor Manager, CBS who coordinated and efficiently implemented all the tasks relating to the SHHS2 and finally the FMOH take this opportunity to pay lots of thanks and gratitude to Mr. K. Ramachandran to excellent job done and his valuable contribution in the report writing..

Dr. Mohamed Ali Yahia Elabassi
SHHS2 National Coordinator

Executive Summary

This Report presents the detailed findings of the Sudan Household Health Survey second round (SHHS2), conducted jointly by the Federal Ministry of Health (FMOH) and The Central Bureau of Statistics with financial and technical assistance from the United Nations agencies and other partners. The SHHS2 is a customized version of the Multiple Indicator Cluster Survey (MICS) Round 4 and the Pan Arab League Household Family Survey (PAPFAM). The survey is part of a worldwide survey program, originally developed to measure progress towards an internationally agreed set of goals that emerged from the 1990 World Summit for Children. This Main Report covers the following areas; sample and survey methodology, sample coverage and the characteristics of households and respondents, child mortality, child nutrition, child health, environment, reproductive health, education, child protection, and HIV and AIDS and orphaned and vulnerable children.

The survey was conducted at a time when Sudan is experiencing the separation with unprecedented socioeconomic challenges which had direct implications on the welfare of children and women.

The national and state-level data generated by the SHHS are expected to help in assessing the current status in relation to some of the key indicators relating to the Millennium Development Goals (MDGs), the World Fit For Children (WFFC) goals, Programme of Action adopted at the International Conference on Population and Development (ICPD), and other internationally and nationally agreed upon goals, as a basis for action.

Sample design and coverage

The sample for the Sudan Household Health Survey (SHHS) was designed to provide estimates in regard to some key indicators at the national level and for 15 states. It was judged that a minimum sample of about 1000 households in each state would be necessary to make survey estimates with the required degree of precision at the state level. A two-stage cluster sampling design was employed to draw the sample in each state. The villages or quarters (in the case of urban areas) constituted the Primary Sampling Units (PSUs). It was decided to draw 40 clusters from each state and 25 households from each cluster. Accordingly, the survey aimed at a total sample of 15,000 households in 15 states of Sudan.

Questionnaires

The survey tools consisted of five sets of questionnaires: (i) a Household questionnaire which was used to collect information on all de jure household members and the household; (ii) a Women's questionnaire administered to all women aged 15-49 years in each household; and (iii) a children's questionnaire administered to mothers or caretakers of all children under five years of age living in the household; (iv) Men's questionnaire administered to men living in the household; and (v) Food Security Questionnaire.

The first three questionnaires are based on the MICS4 and PAPFAM model questionnaires. A copy of the SHHS2 questionnaires is provided in Appendix F.

Background characteristics of Households and respondents

Of the 15,000 households selected for the sample, 14,921 were found to be occupied. Of these, 14,778 households were interviewed successfully for a household response rate of 99.0 per cent. In those households interviewed, 18,614 women (age 15-49 years) were identified. Of these, 17,174 women were interviewed, yielding a response rate of 92.3 per cent within interviewed households. In addition, 13,587 children under age five were listed in the household questionnaire. Questionnaires were completed for 13,282 of these children, corresponding to a response rate of 97.8 per cent. An overall response rate of 91.4 per cent was achieved for women. While an overall response rate of 96.8 per cent was achieved for under-five children (Table 3.1).

Infant and under-five mortality

The infant and under-five mortality rates that have been computed by using the direct estimation method indicate that the infant mortality rate (IMR) in Sudan was 60 per 1,000 live births while the under -5 mortality rate

(U5MR) was 83 per 1000 live births during the 5-year period before the SHHS2. Estimates of neonatal, post-neonatal and child mortality rates have also been made using the direct method. They were respectively 34.45 and 25.78 per 1,000 live births.

Children's nutritional status

Underweight prevalence (moderate and severe): Almost one in three children under age five in Sudan were found to be moderately or severely underweight. There was a slight difference in terms of those who were moderately or severely underweight among boys (33.6 per cent) and girls (30.7 per cent).

Underweight prevalence (severe): Almost one in eight (12.6 per cent) under age five in Sudan could be classified as severely underweight.

Stunting prevalence (moderate and severe): The SHHS2 findings indicated that about 35.0 per cent of children under age five in Sudan were moderately or severely stunted (too short for their age) . cent) and girls (32.6 per cent).

Wasting prevalence (moderate and severe): Approximately one out of six under-five children (16.4 per cent) in Sudan were found to be moderately or severely wasted (too thin for their height). Wasting is usually the result of a recent nutritional deficiency related to, for example, recent illness or inadequate diet intake. The prevalence estimate may exhibit significant seasonal shifts associated with changes in the availability of food or disease prevalence.

Breast feeding

Based on the survey findings, the proportion of children born in the last two years who were ever breastfed, and those who were first breastfed within one hour and one day of birth. Although a very important step in management of lactation and establishment of a physical and emotional relationship between the baby and the mother, only 73.2 per cent of babies were found to have been breastfed for the first time within one hour of birth, while 92.6 per cent of newborns in Sudan started breastfeeding within one day of birth.

The SHHS2 data indicated that about 87.6 percent of children age 12-15 months received continued breastfeeding at one year. The percentage of children age 12-15 months who received continued breastfeeding was higher in urban areas (90.8 per cent) than that of children in rural areas (86.3 per cent).

About 2.5 per cent of children aged 2-3 months were weaned (not breastfed). The percentage of children that were exclusively breastfed was only 18.3 per cent among children aged 4-5 months, though exclusive breastfeeding is considered as adequate feeding up to six months. Few mothers continued breastfeeding up to 23 months. In all, only about 29.4 percent of children aged 22-23 months were receiving breast milk.

Iodized Salt. A very small proportion of households (2.4 per cent), there was no salt available at the time of the survey. The SHHS2 findings indicated that only a very small proportion of households (14.7 per cent) were found to be using iodized salt. In only 9.5 percent of households, salt was found to contain 15 parts per million (ppm) or more of iodine, while in the case of 5.3 percent of households, salt was found to contain less than the required 15 parts per million (ppm).

Vitamin A. The survey results indicate the percent distribution of children aged 6-23 months who received Vitamin A during the last six months preceding the SHHS. Within the six months prior to the SHHS, 60.5 percent of children aged 6-23 months received a high dose Vitamin A supplement. The percentage of children aged 6-23 months that received a high dose Vitamin A supplement was slightly higher for male children (61.2 per cent) than that for female children (59.7 per cent). Similarly, the percentage of children aged 6-23 months that received a high dose Vitamin A supplement was slightly higher for children in urban areas (60.7 per cent) than that for children in rural areas (60.4 per cent).

Child health

Immunization coverage. The SHHS2 data indicated that only half (49.4 per cent) of Sudan's children age 12-23 months were fully immunized with BCG vaccine against tuberculosis, three doses of polio vaccine against polio, three doses of Pentavalent against DPT (diphtheria, pertussis and tetanus), Hepatitis B (HB), and Haemophilus influenza (HIB) and measles vaccine before their first birthday. This leaves the rest of the children age 12-23 months unprotected against life-threatening diseases. The percentage of fully immunized children was slightly higher among females (50.3 per cent) than that among male children (48.5 per cent). The percentage of fully immunized children was higher for children in urban areas (56.2 per cent) than among children in rural areas (46.6 per cent). The percentage of fully immunized children ranged from 41.3 per cent for children of mothers with no education to 58.4 per cent for children of mothers with primary education, and to 60.8 per cent for children of mothers with secondary or higher education.

The SHHS2 data indicates that the percentage of women aged 15-49 years with a live birth in the last two years protected against neonatal tetanus was only 54.7. The percentage of women who received at least two doses of tetanus toxoid (TT) vaccine during last pregnancy was only 34.1 per cent.

Management of diarrhoea. The SHHS2 data indicated that overall, 26.8 percent of under-five children had diarrhoea in the two weeks preceding the survey (Table CH.4). The peak of diarrhoea prevalence (36.3 per cent) was observed among children aged 12-23 months. There was slight difference in the proportion of under-five children who had diarrhoea in the two weeks preceding the survey in rural and urban areas.

Care seeking for suspected pneumonia.

The SHHS2 data indicates that about 18.7 percent of children aged 0-59 months were reported to have had symptoms of pneumonia during the two weeks preceding the survey. Very little difference between boys (18.9 per cent) and girls (18.5 per cent) was observed with regard to suspected pneumonia. There was slight difference with regard to suspected pneumonia between children from urban areas (17.6 per cent) and children from rural areas (19.1 per cent). There was slight difference with regard to suspected pneumonia between children of mothers with no education (18.7 per cent)

Water and Sanitation

The SHHS2 findings indicated that overall, 60.5 per cent of the population was using an improved source of drinking water at the time of the survey. The percentage of household population using an improved source of drinking water was higher for household members in urban areas (66.6 per cent) than that for household members in rural areas (57.7 per cent). The percentage of household population using improved sources of drinking water increases with the educational level of the household head. The percentage of household population using improved sources of drinking water showed an increasing trend from 55.8 per cent in the case of households which had household heads with no education to 62.9 per cent in the case of households which had household heads with primary education and to 72.7 per cent in the case of households which had household heads with secondary or higher level of education. The percentage of household population using improved sources of drinking water also increases with the family wealth.

The SHHS2 findings indicated that 35.1 per cent of the population of Sudan were living in households using improved sanitation facilities. This percentage was 60.2 per cent in urban areas compared to 23.4 per cent in rural areas. The proportion of household members using improved sanitation facilities was highest in Khartoum State (67.9 percent) and the lowest in Blue Nile State (5.7 per cent)

Reproductive Health

The SHHS2 data indicated that 13.4 per cent of women age 15-19 years has already had a birth, 2.9 per cent were pregnant with their first child, 16.3 per cent have begun childbearing and 1.2 per cent has had a live birth before age 15. The SHHS findings also indicated that 14.0 per cent of women aged 20-24 have had a live birth before age 18.

Percentage of women with a live birth before age 15 years: The SHHS2 findings indicated that about 1.2 per cent of women have had a live birth before age 15 and The SHHS2 findings indicated that about 14.0 per cent of women have had a live birth before age 18. There were some differences in percentage of women in urban and rural areas who have had a live birth by age 18.

Contraception. Table 8.3 provides information on the use of contraception. It indicates the percentage of women age 15-49 years currently married who are using (or whose partner is using) a contraceptive method. Current use of contraception was reported by 9.0 per cent of women currently married. The most popular method is the pill which is used by 6.3 per cent of married women in Sudan. The next most popular method was the use of injectable, which accounted for 0.9 per cent of married women. About 0.5 per cent of women reported use of the IUD

Unmet need. The SHHS2 findings indicated that the percentage of women age 15 - 49 years (currently married) with unmet need for contraception for spacing and limiting were 18.4 per cent and 10.5 percent respectively. The unmet need for contraception varied marginally by urban/rural areas. The unmet need for contraception for spacing was 17.5 per cent in the case of women in urban areas compared to 18.8 per cent for women in rural areas. The unmet need for contraception for limiting was 11.9 per cent in the case of women in urban areas compared to 9.8 per cent for women in rural areas

Antenatal care. In the country as a whole, about a quarter of women (25.7 per cent) age 15-49 years who gave birth in the two years preceding the survey received no antenatal care from qualified health personnel (a doctor, nurse, health visitor or midwife). About 46.9 per cent of women received ANC from a medical doctor, 3.6 per cent received ANC from a nurse, 5.4 per cent from a health visitor and 18.4 per cent from a midwife.

Place of delivery. The SHHS2 findings indicated that about 20.5 per cent of births in Sudan (North) were delivered in a health facility; 19.6 per cent of deliveries occurred in a hospital and 0.9 per cent occurred in a primary health care facility (PHCF). Three in four births (76.0 per cent) occurred at home. Women in urban areas (36.1 per cent) were more likely to deliver in a health facility compared to their rural counterparts (13.3 per cent).

Literacy and Education

The SHHS2 data indicated that the literacy rate among young women remains low. Nationwide, only 45.2 per cent of women age 15-24 years was literate. The percentage of literate women age 15-24 years was higher in urban areas (56.6 per cent) than that among women in rural areas (39.0 per cent). Of women who stated that primary school was their highest level of education, only 52.0 per cent of them were actually able to read the statement shown to them while of the women who stated that secondary school was their highest level of education, 71 per cent of them were able to read the statement shown to them.

Primary school entry (Net intake rate in primary education): Table 9.4 provides information regarding the net intake rate in primary education, i.e. percentage of children of primary school entry age entering grade I in primary school. Of children who were of primary school entry age (age 6) in Sudan, about 46.0 per cent of them were attending the first grade of primary school at the time of the SHHS2. Of male children who were of primary school entry age, 46.9 per cent of them were attending the first grade of primary school compared to 45.1 per cent of female children of primary school entry age.

The SHHS2 data indicate that about 71.8 per cent of children of primary school age were attending school at the time of the survey. This means that about 28.2 per cent of the children were out of school when they were expected to be participating in primary education. The percentage of children of primary-school age attending school at the time of the survey was highest (81.9 per cent) among children aged 10 years and lowest among children aged 6 years (49.4 per cent).

At the time of the SHHS2, the primary school completion rate was 62.7 per cent (71.6 per cent for boys and 54.9 per cent for girls). The primary school completion rate was 92.4 per cent for children in urban areas compared to 49.4 per cent for children in rural areas.

Birth registration

The SHHS2 data indicated that the births of 59.3 percent of under-five children in Sudan were reported registered on the reference date of the survey. Of the children under age five whose birth was not registered, mothers/caretakers of 26.3 per cent of these children knew how to register birth.

Early marriage and polygyny

The SHHS2 data indicated that about one in ten (9.5 per cent) young women married before age 15. The proportion of young women who were married before age 15 varied between urban and rural areas. Nationwide, about 20.0 per cent of women age 15-49 years were in Polygamous marriage. This percentage was lower among women in urban areas (15.3 per cent) than that among women in rural areas (22.1 per cent). The incidence of polygamy appears to be linked to women's education level and the household wealth.

Female Genital Mutilation/Cutting

The SHHS2 data shows that 87.6 per cent of women aged 15-49 and 65.5 per cent of ever women aged 0-50+ had some form of genital cutting. The percentage of women who had been subjected to FGM/C was highest (89.8) among women in the age group 40-44 years and lowest (9.2) among girls in the age group 0-4 years. Younger women are less likely to have undergone any form of FGM/C than women in the older age groups, and fewer girls are circumcised due to age, however the gap between the girls and women due to age has to be taken with caution.

Attitudes toward domestic violence

The responses to SHHS2 questions are indicated in Table 10.10. Overall, 47.0 per cent of women in Sudan feel that their husband/partner has a right to hit or beat them for at least one of a variety of reasons.

Prevalence of orphans

Nationwide, the prevalence of orphans (percentage of children under age 18 who have one or both of their parents dead) was 5.7 per cent. There was only a marginal difference in the percentage of children who had one or both of their parents dead between female children (5.7 per cent) and male children (5.6 per cent). The proportion of children who had one or both of their parents dead was marginally higher in urban areas (6.5 per cent) than that in rural areas (5.3 per cent).

HIV/AIDS knowledge and attitude

Women age 15-49 years who have heard about AIDS: The SHHS2 data indicated that overall, more than three-fourths (76.4 per cent) of women age 15-49 years have heard of AIDS.

The SHHS2 findings indicated that 62.0 per cent of women age 15-49 years knew of having one faithful uninfected sex partner and 17.2 per cent of them knew of using a condom every time during sexual intercourse as main ways of preventing HIV transmission.

Overall, 36.2 per cent of women age 15-49 years knew that a healthy looking person could have the AIDS virus. The proportion of women who knew that a healthy looking person could have the AIDS virus was higher among women in urban areas (54.9 per cent) than among women in rural areas (26.5 per cent).

Overall, only 5.8 per cent of women were found to have comprehensive knowledge of HIV prevention, which was higher among women in urban areas (11.4 per cent) than among women in rural areas (3.0 per cent). The proportion of women who had comprehensive knowledge about HIV prevention was highest among women in the age group 30-39 years (7.2 per cent) and lowest among women in the age group 40-49 years (4.4 per cent).

Injury and Chronic diseases

The SHHS2 data indicates that the major chronic diseases that are prevalent among people of Sudan and the percent distribution of respondents according to diseases are as follows: Hypertension (24.3 per cent), Diabetes (14.5 per cent), Asthma (8.1 per cent), Hypothyroidism (6.6 per cent), Glaucoma (6.3 per cent), Cataract (4.7 per cent), Mental health-related problems (3.0 per cent), Heart disease (2.7 per cent), Rheumatic heart disease (2.7 per cent), Renal failure (2.4 per cent), TB (1.5 per cent), Epilepsy (1.3 per cent), cancer (0.3 per cent), Leprosy (0.2 per cent) and other diseases (30.6 per cent).

Food security

Diets in Sudan are diverse, linked in large part to its climatic conditions and resource base. The main dietary sources for people in Sudan include cereal, sugar, oil, milk, meat, pulses, vegetables, fruits and eggs. Though the main staples of the Sudanese diet are sorghum and millet, in certain areas, especially in pastoral areas, there is a significant amount of meat and milk consumed as well.

The SHHS2 data indicated that a total of about 8.4 per cent of households were moderately or severely food insecure. The proportion of moderately and severely food insecure households ranged between 0.4 per cent in River Nile State and 20.1 per cent in West Darfur State.

I. Introduction

Background

Administratively, the Sudan is governed by a federal system, comprising of 15 States. Sudan neighbours seven countries – Central African Republic, Chad, Egypt, Eritrea, Ethiopia, Libya, and Republic of South Sudan -

Sudan Household Survey (SHHS2)

The Government's efforts aimed at formulating and implementing policies and programmes that would have a positive impact on the situation of children and women in Sudan in particular, and on the achievement of the MDGs in general, necessitates periodic collection of relevant data/information for assessing progress towards achievement of the defined developmental goals and targets. The Sudan Household Survey represents one of the major tools to make available the data/information required for assessing progress towards achievement of the defined national and international developmental goals and targets and for the formulation and implementation of policies and programmes to improve the situation of children and women in Sudan.

Sudan has been conducting surveys to generate data on important indicators for assessing progress towards developmental targets. Some of these surveys conducted earlier include the Demographic and Health Survey (DHS) carried out in 1989-90, a Maternal and Child Health survey which was conducted in 1993 (Sudan, Ministry of Health, 1994) under the Pan Arab Project on Child Development (PAPCHILD), Safe Motherhood Survey (SMS) of 1999, conducted by the Central Bureau of Statistics under the overall supervision of the Federal Ministry of Health. The SMS was followed by the Multiple-Indicator Cluster Survey (MICS) of 2000 covering all northern states and selected urban areas of three states in Southern Sudan.

The Sudan Household Health Survey (SHHS), conducted in 2006, was the first nationally representative survey covering the whole of Sudan in two decades covering key social development indicators. The national and state-level data generated by the SHHS helped in creating a baseline for assessing the progress towards some of the key MDG goals and targets, assisting in monitoring of MDG commitments and in informed decision making in regard to development planning.

The Sudan Household Health Survey - Second Round (SHHS2) conducted during the period March to May 2010 by the Federal Ministry of Health (FMOH) and the Central Bureau of Statistics (CBS), Government of Sudan represents a major effort on the part of the Government of Sudan to assess the situation of children and women and to monitor progress towards selected national development goals and the Millennium Development Goals (MDGs) and targets. The survey was carried out in collaboration with several ministries and institutions of the Government of Sudan as well as regional and international organisations such as the United Nations Children's Fund (UNICEF), the United Nations development Programme (UNDP), the World Health Organisation (WHO), the United Nations Population Fund (UNFPA), the World Food Programme (WFP), the United States Agency for International Development (USAID), the Pan Arab Project for Family Health (PAPFAM).

Survey Objectives

The primary objectives of the 2010 Sudan Household Health Survey (SHHS2) were as follows:

- To provide up-to-date information for assessing the situation of children and women in Sudan;
- To furnish data needed for monitoring progress toward goals established in the Millennium Declaration and other internationally agreed upon goals, as a basis for future action;
- To contribute to the improvement of data and monitoring systems in Sudan and to strengthen technical expertise in the design, implementation, and analysis of such systems.

- To generate data on the situation of children and women, including the identification of vulnerable groups and of disparities, to inform policies and interventions.

The methodology and content of SHH2 are based on the models and standards developed by the global Multiple Indicator Cluster Survey (MICS) project, an international household survey programme developed and supported by UNICEF. The SHHS2 was conducted as part of the fourth round of MICS. The SHHS2 provides valuable information on the situation of children and women in Sudan, and measures of key indicators that allow Sudan to monitor progress towards the goals and targets emanating from some of the international agreements: the Millennium Declaration, adopted by all 191 United Nations Member States in September 2000, and the Plan of Action of A World Fit For Children, adopted by 189 Member States at the United Nations Special Session on Children in May 2002. Both of these commitments build upon promises made by the international community at the 1990 World Summit for Children.

II. Sample and Survey Methodology

Sample Design

The sample for the Sudan Household Health Survey (SHHS) was designed to provide estimates on some key indicators on the situation of children and women at the national level and for 15 states (Northern, River Nile, Red Sea, Kassala, Gedarf, Khartoum, Gezira, Sinnar, Blue Nile, White Nile, North Kordofan, South Kordofan, North Darfur, West Darfur, South Darfur). The target universe for the SHHS includes the households and members of individual households, including nomadic households camping at a location/place at the time of the survey. The population living in institutions and group quarters such as hospitals, military bases and prisons, were excluded from the sampling frame.

The states constitute the main sampling domains and in each state a two stage cluster sampling design was employed to draw the sample for the SHHS. The villages or quarters (in the case of urban areas) constituted the Primary Sampling Units (PSUs) for the SHHS. The PSU represented the smallest area or administrative unit which could be identified in the field with commonly recognized boundaries. The sampling frame for 15 states was compiled using the list of villages and quarters and estimated population updated by the Central Bureau of Statistics on the basis of the updated frame from the 2008 Population Census. The 15 states clusters were distributed to urban and rural areas, proportional to the size of urban and rural populations in each state. The urban and rural clusters in each of these states were selected randomly with probability of selection proportional to size.

The sample size for the survey was determined by the accuracy and degree of precision required for the survey estimates for each state. It was judged that a minimum sample of 900 households would be necessary to make estimates/results with some degree of precision at the state level. Allowing for some non-response in the survey, it was decided to take a sample of 1,000 households in each state. Since a similar level of precision was required for the survey results from each state, it was decided to draw 40 clusters from each state and 25 households from each cluster. The sampling frame of villages/quarters was compiled separately for each state based on the best available population measures. In cases where a selected village/quarter could not be reached because of security or access problems, it was replaced by a neighboring village/quarter in the sampling frame. All selected clusters (villages/quarters) in each state were fully covered. After a household listing was carried out within the selected clusters, a sample of 25 households was drawn from each selected cluster using the method of systematic random sampling.

Although each state sample can be considered as self-weighting, the total sample for Sudan is not self-weighting since a fixed sample of households was drawn from each state, irrespective of its population size. Therefore, to derive estimates for Sudan as a whole it was necessary to assign a weight to each state-level sample. For reporting national level results, and to obtain unbiased estimates from the data, appropriate weights were applied to the sample data based on the probabilities of selection. Measures of sampling variability for key survey estimates were also calculated. Sample weights were calculated for each state-level sample and these were used in the subsequent analyses of the survey data.

The formula used for the calculation of the sample size was:

$$n = z^2 * (P) (1-p) (1 + NRR) (deff) / (d^2)(h)$$

Where:

n = the required sample size, (number of households)

z = the value in the normal distribution that gives a level of confidence at 95% (z = 1.96)

p = for the key indicator selected = 0.05.

deff = the design effect, (deff = 2)

d = the desired margin of error, (d = 0.01).

NRR= non-response rate, NRR= 30% (0.3).

h = Household size

For the calculation of the sample size, p was assumed to be 5 percent. The value of d_{eff} (design effect) was taken as 2 based on estimates from previous surveys, and average household size was taken as 6 individuals. The estimated sample size was approximately 863 households per state. Though an effective sample size of 900 households was considered sufficient for most state-level estimates, it was decided to target 1,000 households in each state, thus yielding a total of about 15,000 households nationally. The average cluster size in the SHHS was determined as 25 households, based on a number of considerations, including the budget available, and the time that would be needed per team to complete data collection in one cluster. Equal allocation of the total sample size to the 15 states was targeted. Therefore, 40 clusters were allocated to each state, with the final sample size calculated at 15,000 households (i.e., 40 clusters x 15 states x 25 households per cluster).

Questionnaires

The survey tools consisted of five sets of questionnaires: (i) a **Household questionnaire** which was used to collect information on all *de jure* household members (usual residents), the household and the dwelling; (ii) a **Women's questionnaire** administered to all women aged 15-49 years in each household; (iii) a children's **questionnaire** administered to mothers or caretakers of all children under five years of age living in the household; (iv) a men's questionnaire administered to all men aged 15-49 years living in the household; and (v) **Food Security Questionnaire**.

The first three questionnaires are based on the MICS4 and PAPFAM model questionnaires. A copy of the SHHS2 questionnaires is provided in Appendix F.

The **Household Questionnaire** included the following modules:

- Household listing form;
- Education;
- Chronic diseases and injuries (country specific module);
- Female Genital Mutilation/Cutting (FGM/C) (country specific module);
- Child disability;
- Water and sanitation
- Household characteristics/income;
- Insecticide treated nets (ITNs);
- Salt iodization

The **Questionnaire for Individual Woman** included the following modules:

- Woman's Background;
- Marriage
- Child Mortality
- Desire For Last Birth;
- Birth History
- Maternal and newborn Health;

- Contraception;
- Unmet Need;
- Female Genital Mutilation/Cutting (FGM/C) (country specific module);
- Attitude Towards Domestic Violence;
- HIV/AIDS Knowledge,
- Sexually Transmitted Infections (STI) (country specific module).

The Questionnaire for Children under five years of age was administered to mothers of under-five children. In cases when the mother was not listed in the household list/roster, a primary caretaker for the child was identified and interviewed. The **Questionnaire for Children under Five** included the following modules:

- Age;
- Birth registration;
- Early childhood development(country specific module);
- Care of illness and Illness Symptoms
- Vitamin A;
- Malaria;
- Breastfeeding;
- Immunisation;
- Anthropometry.

The **Questionnaire for Individual Men** included the following modules:

- Man's background;
- Marriage;
- Approval for FGM;
- Condom use
- Sexually Transmitted Infections (STI);
- HIV/AIDS knowledge, including sexual behaviour;

The **Food Security Questionnaire** included the following modules:

- Income sources;
- Household expenditures;
- Food consumption and dietary diversity.

In addition to the administration of questionnaires, fieldwork teams tested the salt used for cooking in the households for iodine content, tested blood for HH members and measured the weights and heights of children under five years of age. Details and findings of these measurements are provided in the respective sections of the report.

Training and Fieldwork

The questionnaires were pre-tested during the last quarter of 2009 and the first quarter of 2010 and modifications were made to the wording and translation of the questionnaires based on the results of the pre-test.

Training programmes for the fieldwork were conducted for all the states involved in the SHHS2 during the month of February and March 2010, the duration of training varying between 7-10 days. The training was conducted at three levels -- national, sub-national and state levels. To ensure consistency, the sub-national training sessions for all trainees in all states were conducted by the same trainers. The training included lectures and discussions relating to interviewing techniques and the contents of the questionnaires, supervision and monitoring of quality of data. Towards the end of the training period, trainees spent some days in the field to practice interviewing in selected states.

A total of 240 interviewers and 60 supervisors were trained to collect data. Field work was undertaken from March to May 2010. The average period to complete the field work was 33 days, with a minimum of 27 days for the main questionnaires excluding MM survey and a maximum of 43 days, extended to overcome the low response rate, for blood collection and for covering additional clusters for collecting data on maternal mortality.

The data were collected by --- cluster teams in the 15 States of Sudan, involving at least four teams for each of the States. Each cluster team comprised of four interviewers (including the measurer), one field editor, one

blood sample officer and the supervisor. In all, the data collection involved ---- interviewers, and --- team leaders and supervisors, and --- national supervisors and leaders.

Data Processing

Data were entered using the CSPro software. In order to ensure quality control, all questionnaires were double entered and internal consistency checks were performed. Procedures and standard programmes developed under the global MICS4 project and adapted to the SHHS2 questionnaires were used throughout. Data processing was concluded in August -2010. Data were analysed using the Statistical Package for Social Sciences (SPSS) software programme (Version 18), and the model syntax and tabulation plans developed for the SHHS2 based on MICS Syntax.

III. Sample Coverage and the Characteristics of Households and Respondents

Sample Coverage

Of the 15,000 households selected for the sample, 14,921 were found to be occupied. Of these, 14,778 households were interviewed successfully for a household response rate of 99.0 per cent. In those households interviewed, 18,614 women (age 15-49 years) were identified. Of these, 17,174 women were interviewed, yielding a response rate of 92.3 per cent within interviewed households. In addition, 13,587 children under age five were listed in the household questionnaire. Questionnaires were completed for 13,282 of these children, corresponding to a response rate of 97.8 per cent. An overall response rate of 91.4 per cent was achieved for women, while an overall response rate of 96.8 per cent was achieved for under-five children (Table 3.1).

The sample response rates to some extent by urban –rural and by states. Rural areas shows little variations for household, women and children than those of urban area. The response rate among the states for the three questionnaire does not show notable differences between the states. The women's overall response rate was also higher in rural areas (93.1 per cent) than that in urban areas (90.6 per cent). The overall response rate for under-five children was 97.2 per cent in rural areas compared to 95.9 per cent in urban areas. The overall response rate for women's questionnaire was 92.3 in rural areas compared to 89.4 per cent in urban areas.

In the interviewed households, 16,448 men (age 15-49 years) were identified. Of these, only 5,573 men could be successfully interviewed, yielding a response rate of 33.9 per cent within interviewed households. Overall response rate of 33.6 per cent was calculated for the men's interviews (Table 3.1). One of the reasons for the low response rate for men was that at the time of visit to the households by the interviewer, men in a large proportion of the households were out on work. The relatively lower response rate for men implies that the results for men in regard to relevant indicators cannot be presented as they will not be representative.

70-74	544	1.3	443	1.0	988	1.2
75-79	280	.7	202	.5	482	.6
80-84	243	.6	220	.5	463	.5
85+	151	.4	126	.3	277	.3
Missing/DK	21	.1	24	.1	45	.1

0-14	19441	47.1	19084	44.2	38525	45.6
15-64	19991	48.4	22699	52.5	42690	50.5
65+	1860	4.5	1410	3.3	3270	3.9
Missing/DK	21	.1	24	.1	45	.1
Children and adult populations						
Children age 0-17 years	21663	52.4	21315	49.3	42978	50.8
Adults age 18+ years	19630	47.5	21878	50.6	41508	49.1
Missing/DK	21	.1	24	.1	45	.1
Total	41314	100.0	43217	100.0	84530	100.0

The total number of children in the age group 0-17 years in the households and survey population was 42,978 (Male: 21,663; Female: 21,315), constituting 50.8 per cent of the total survey population, the sex ratio being 984 girls for 1,000 boys. The household members aged 18 years and above constituted 49.1 per cent of the survey population. The under-five children in the total survey population was 13,823 (Male: 7,021; Female: 6,802). The proportion of under-five children in the total survey population was estimated at 16.4 per cent, the sex ratio being 969 females for 1,000 males.

The proportion of children in the age group 0-17 years (50.8 per cent) in the total survey population was higher than the proportion of under-18 population (48.5 per cent) at the time of the 2008 Census. The percentage of female household members (51.1 per cent) to total survey population was also higher than the percentage of female population to total population at the time of the 2008 Census (49.0 per cent). Similarly, the percentage of under-five children to total survey population was also higher (16.4 per cent) than the percentage of under-five children to total population at the time of the 2008 Census.

The data in Table HH.2 are also used to produce Figure HH.2 which depicts the age and sex distribution of the household population by five-year age groups.

The above figure (demographic pyramid) shows the age structure of the survey population. The pyramid consists of two sets of horizontal bar graphs, one for each sex, which indicates the proportion of people in each age group. The pyramid shows that the proportion of males is larger than that of females, except in those groups aged 10-14, 15-19, 20-24, 25-29, 30-34, 35-39, and 50-54 years.

Household Composition

Table 3.3 - 3.5 provide basic information on the households, female respondents age 15-49 years, and children under-five by presenting the unweighted, as well as the weighted numbers. Information on the basic characteristics of households, women and children under-five interviewed in the survey is essential for the interpretation of findings presented later in the report and also can provide an indication of the representativeness of the survey. The remaining tables in this report are presented only with weighted numbers. See Appendix A for more details about the weighting.

Table 3.3 provides basic background information on the households. Within households, the sex of the household head, state of residence, area of residence, number of household members, education of household head and household distribution by age group are shown in the Table 3.3. These background characteristics are used in subsequent tables in this report; the figures in the table are also intended to show the number of observations by major categories of analysis in the report.

The weighted and unweighted numbers of households are equal, since sample weights were normalized (See Appendix A). The table also shows the proportions of households with at least one child under 18, at least one child under 5, and at least one eligible woman age 15-49 years. The table also shows the weighted average household size estimated by the survey.

of them had secondary or higher level of education. The members in the households in urban areas constituted 29.5 per cent of the total household members while household members in rural areas constituted 70.5 per cent of the total household members.

The households with four members constituted the largest proportion (14.6 per cent) of the surveyed households followed by households with five members (14.5 per cent) and households with six members (14.1 per cent) while households with only one member constituted the least proportion (1.6 per cent) of all households. This indicates that a large proportion of households/families had four or more than four members which reflect the preference for larger families among a majority (78.3 per cent) of the households. The SHHS2 findings indicate that smaller households (with three or less than three members) constitute a very small proportion (21.7 per cent).

About 58.1 per cent of the households had at least one child under five while 85.2 per cent of the households had at least one child under 18. About 89.7 per cent of the households had at least one woman in the age group 15-49 years while 75.4 per cent of the households had at least one man in the age group 15-49 years. The weighted average household size estimated by the survey was 5.7.

Characteristics of Female Respondents 15-49 Years of Age and Children Under-5

Table 3.4 provides information on the background characteristics of female respondents 15-49 years of age. The table includes information on the distribution of women according to state of residence, area of residence, age group, marital status, motherhood status, births in last two years preceding the SHHS, educational status¹, and wealth index quintiles².

Of the total women in the age group 15-49 years in the survey population, women in urban areas constituted 34.0 per cent of total women in the survey population while women in rural areas constituted 66.0 per cent. Women in the age group 15-19 years constituted the largest proportion (20.7 per cent) of women in the survey population followed by women in the age group 20-24 years (19.3 per cent) and those in the age group 25-29 years (18.5 per cent) while the lowest proportion of women was in the age group 45-49 years (6.2 per cent).

About 64.1 per cent of the women aged 15-49 years were currently married and 5.7 per cent were formerly married (widowed, divorced or separated) while never married women constituted 30.2 per cent. Approximately six out of ten (62.3 per cent) women had given birth to a child while 37.6 per cent never gave birth to a child. About 32.9 per cent of the women age 15-49 years had a birth in last two years preceding the SHHS2. Women with no formal education made up 35.3 per cent of the total women in the survey population while 32.4 per cent had primary education and 28.0 per cent had secondary or higher level of education. The results in regard to wealth index quintiles show that about 17.5 per cent of women belonged to households in the poorest quintile while women from households in the richest quintile constituted about 23.3 per cent.

¹ Unless otherwise stated, "education" refers to educational level attended by the respondent throughout this report when it is used as a background variable.

² Principal components analysis was performed by using information on the ownership of consumer goods, dwelling characteristics, water and sanitation, and other characteristics that are related to the household's wealth to assign weights (factor scores) to each of the household assets. Each household was then assigned a wealth score based on these weights and the assets owned by that household. The survey household population was then ranked according to the wealth score of the household they are living in, and was finally divided into 5 equal parts (quintiles) from lowest (poorest) to highest (richest). The wealth index is assumed to capture the underlying long-term wealth through information on the household assets, and is intended to produce a ranking of households by wealth, from poorest to richest. The wealth index does not provide information on absolute poverty, current income or expenditure levels. The wealth scores calculated are applicable for only the particular data set they are based on. Further information on the construction of the wealth index can be found in *Filmer, D. and Pritchett, L., 2001. "Estimating wealth effects without expenditure data – or tears: An application to educational enrolments in states of India". Demography 38(1): 115-132. Gwatkin, D.R., Rutstein, S., Johnson, K., Pande, R. and Wagstaff, A., 2000. Socio-Economic Differences in Health, Nutrition, and Population. HNP/Poverty Thematic Group, Washington, DC: World Bank. Rutstein, S.O. and Johnson, K., 2004. The DHS Wealth Index. DHS Comparative Reports No. 6. Calverton, Maryland: ORC Macro.*

Children under the age of five years constituted about 16.4 per cent of the total survey population. Male children constituted 50.8 per cent of the total number of under-five children while female children constituted 49.2 per cent. The proportion of under-five children in urban areas was 27.6 per cent of the total under-five children in the survey population while the proportion of under-five children in rural areas was 72.4 per cent. Children age 36-47 months constituted the largest proportion (21.2 per cent) of under-five children followed by children age 24-35 months (20.8 per cent) and children age 12-23 months (19.7 per cent) while the lowest proportion of under-five children was in the age group 6-11 months (10.6 per cent). Under-five children whose mothers had no formal education constituted 55.4 per cent, while 30.4 per cent of under-five children had mothers with primary education and 13.4 per cent had mothers with secondary or higher level of education. The data relating to the wealth index quintiles showed that about 24.2 per cent of under-five children belonged to households in the poorest quintile while children from households in the richest quintile constituted about 14.1 per cent.

34 per thousand live births among children living in rural areas. The NMR among children of mothers from households in the poorest quintile was highest at 38 per thousand live births compared to 20 per thousand live births among children of mothers from households in the richest quintile.

Post-neonatal mortality rate (PNMR): The post-neonatal mortality rate (PNMR) was estimated at 26 per thousand live births. There was no difference in PNMR between males and females. The PNMR among children of mothers from households in the second wealth quintile was highest at 31 per thousand live births compared to 18 per thousand live births among children of mothers from households in the richest quintile.

Infant mortality rate (IMR): The infant mortality rate (IMR) was estimated at 60 per thousand live births. The IMR was much higher for males (66 per thousand live births) than females (54 per thousand live births). No difference in IMR between infants living in urban and rural areas was noted. The IMR among infants of mothers in the second wealth quintile was highest at 69 per thousand live births 37 per thousand live births among children of mothers from households in the richest quintile.

Child mortality rate (CMR): The Child mortality rate (CMR) was estimated at 24 per thousand live births. The CMR was higher for children living in rural areas (26 per thousand live births) than for children living in urban areas (18 per thousand live births). The CMR among children of mothers from households in the second wealth quintile was highest at 30 per thousand live births compared to 5 per thousand live births among children of mothers from households in the richest quintile.

Under-five mortality rate (U5MR): The under-five mortality rate (U5MR) was estimated at 83 per thousand live births. The U5MR was much higher for males (89 per thousand live births) than females (76 per thousand live births). The U5MR was higher for children living in rural areas (84 per thousand live births) than for children living in urban areas (79 per thousand live births). The U5MR among children of mothers from households in the second wealth quintile was highest at 97 per thousand live births compared to 42 per thousand live births among children of mothers from households in the richest quintile.

The SHHS findings imply that a child born into households in the poorest quintile is approximately twice as likely to die by his/her fifth birth day as those born into households in the richest quintile.

V. Nutrition

Children's Nutritional Status

Children's nutritional status is a reflection of their overall health. When children have access to an adequate food supply, are not exposed to repeated illness, and are well cared for, they reach their growth potential and are considered well nourished.

The nutrition program in Sudan is aimed at reducing child mortality associated with malnutrition in the short-term as well as preventing malnutrition and its life-long effects in the long-term. Program interventions include food fortification initiatives, promotion of exclusive breastfeeding for the first six months of life and other good infant feeding practices, mass Vitamin A supplementation for children and pregnant and lactating women, as well as treatment of severe and moderate acute malnutrition. The nutrition situation is monitored through locality and state level surveys, a community-based nutrition surveillance system and on-going data collection from feeding programs and health facilities.

The Millennium Development Goal target is to reduce by half the proportion of people who suffer from hunger between 1990 and 2015. One of the indicators for measuring progress towards this target is *underweight prevalence (moderate and severe)* i.e. proportion of children under age five who fall below minus two standard deviations from the median weight-for-age of the WHO growth standards. A reduction in the prevalence of malnutrition is also expected to contribute to the achievement of the goal of reducing child mortality.

In a well-nourished population, there is a reference distribution of height and weight for children under age five. Under-nourishment in a population can be gauged by comparing children to a reference population. The reference population used in this report is based on the WHO growth standards³. Each of the three nutritional status indicators— *weight for age*, *height for age* and *weight for height* - can be expressed in standard deviation units (z-scores) from the median of the reference population.

Weight-for-age is a measure of both acute and chronic malnutrition. Children whose weight for age is below minus two standard deviations from the median weight for age of the WHO growth standard are considered *moderately or severely underweight* while those whose weight for age is below minus two standard deviations from the median weight for age of the WHO growth standard are classified as *severely underweight*.

Height-for-age is a measure of linear growth. Children whose height for age is below minus two standard deviations from the median weight for age of the WHO growth standard are considered short for their age and classified as *moderately or severely stunted*. Those whose height for age is below minus three standard deviations from the median weight-for-age of the WHO growth standard are classified as *severely stunted*. Stunting is a reflection of chronic malnutrition as a result of failure to receive adequate nutrition over a long period and recurrent or chronic illness.

³ http://www.who.int/childgrowth/standards/second_set/technical_report_2.pdf

In 2006, WHO published child growth standards for attained weight and height to replace the previously recommended 1977 NCHS/WHO child growth reference. These new standards are based on breastfed infants and appropriately fed children of different ethnic origins raised in optimal conditions and measured in a standardized way. The same cohort was used to produce standards of mid-upper arm circumference (MUAC) in relation to age. The new WHO growth standards confirm earlier observations that the effect of ethnic differences on the growth of infants and young children in populations is small compared with the effects of the environment. Studies have shown that there may be some ethnic differences among groups, just as there are genetic differences among individuals, but for practical purposes they are not considered large enough to invalidate the general use of the WHO growth standards population as a standard in all populations. These new standards have been endorsed by international bodies such as the United Nations Standing Committee on Nutrition, the International Union of Nutritional Sciences and International Paediatric Association and adopted in more than 90 countries.

Weight-for-height represents a measure of wasting. Children whose *weight for height* is below minus two standard deviations from median weight for height of the WHO growth standard are classified as *moderately or severely wasted*, while those whose *weight-for-height* is below minus three standard deviations from median weight for height of the WHO growth standard are classified as *severely wasted*. Wasting is usually the result of a recent nutritional deficiency. The indicator may exhibit significant seasonal shifts associated with changes in the availability of food or disease prevalence.

Finally, the weight for height z-scores (WHZ) and the presence of bilateral pitting oedema among children age 6-59 months provides a measure of acute malnutrition in the population. This is conventionally expressed in terms of Global Acute Malnutrition (GAM) prevalence, Moderate Acute Malnutrition (MAM) prevalence and Severe Acute Malnutrition (SAM) prevalence. Indicators of acute malnutrition (GAM, MAM and SAM) prevalence are estimated on the basis of the weight for height z-scores (WHZ) and/or oedema in regard to children age 6-9 months. Global Acute Malnutrition (GAM) is defined in terms low weight for height z-scores ($<-2SD$ from the median weight for height of the WHO growth standard) and/or oedema. Moderate Acute Malnutrition (MAM) is defined in terms low weight for height z-scores ($<-2SD$ and $>_3SD$ from the median weight for height of the WHO growth standard) and no oedema, while Severe Acute Malnutrition (SAM) is defined in terms very low weight for height z-scores ($<-3SD$ from the median weight for height of the WHO growth standard) and/or oedema.

In SHHS2, weights and heights of all children under five years of age were measured using anthropometric equipment recommended by UNICEF (www.childinfo.org). Findings in this section are based on the results of these measurements.

Table 5.1 shows the percentages of children aged 0-59 months who were classified into each of the above mentioned categories, based on the anthropometric measurements that were taken during fieldwork. It presents the underweight, stunting and wasting prevalence rates among under-five children. Additionally, the table includes the percentage of children who were found to be overweight, which takes into account those children whose weight for height is above two standard deviations from the median of the reference population, and mean z-scores for all three anthropometric indicators.

Children whose full birth date (month and year) were not obtained, and children whose measurements were outside a plausible range are excluded from Table 5.1. Children are excluded from one or more of the anthropometric indicators when their weights and heights have not been measured, whichever applicable. For example if a child has been weighed but his/her height has not been measured, the child is included in underweight calculations, but not in the calculations for stunting and wasting. Percentages of children by age and reasons for exclusion are shown in the data quality tables DQ.6 and DQ.7.

Underweight prevalence

Underweight prevalence (moderate and severe): Almost one in three children (32.2 per cent) under age five in Sudan were found to be moderately or severely underweight (Table 5.1). There was a slight difference in terms of those who were moderately or severely underweight among boys (33.6 per cent) and girls (30.7 per cent). The proportion of moderately or severely underweight children was higher in rural areas (35.4 per cent) than in urban areas (23.6 per cent). The percentage of children classified as moderately or severely underweight decreases with increasing levels of education of the mother. For instance, the percentage of moderately or severely underweight children was 35.9 among children of mothers with no formal education compared to 29.4 among children of mothers with primary education and 23.2 among children of mothers with secondary or higher levels of education. The percentage of children classified as moderately or severely underweight also decreases with increasing levels of economic status of the households. The percentage of moderately or severely underweight children was 40.0 for children from households in the poorest quintile compared to 16.5 for children belonging to households in the richest quintile. The proportion of children who were moderately or severely underweight was lowest in Khartoum State (19.9 per cent) and the highest in Red Sea State (49.2 per cent) (Table 5.1 and Figure 5.1).

Underweight prevalence (severe): Almost one in eight (12.6 per cent) under age five in Sudan could be classified as severely underweight (Table 5.1). There was a marginal difference in terms of those who were severely underweight among boys (13.7 per cent) and girls (11.4 per cent). The proportion of severely underweight children was higher in rural areas (14.0 per cent) than in urban areas (8.7 per cent).

cent). The percentage of children classified as severely underweight decreases with increasing levels of education of the mother. For instance, the percentage of severely underweight children was 15.1 among children of mothers with no formal education compared to 10.6 among children of mothers with primary education, and 6.8 among children of mothers with secondary or higher levels of education. The percentage of severely underweight children also decreases with increasing levels of economic status of the households. The percentage of severely underweight children was 15.6 among children from households in the poorest quintile compared to 5.8 among children belonging to households in the richest quintile. The proportion of children who were severely underweight was lowest in Khartoum State (6.1 per cent) and the highest in Red Sea State (32.7 per cent) (Table 5.1 and Figure 5.2)

Stunting prevalence

Stunting prevalence (moderate and severe): The SHHS2 findings indicated that about 35.0 per cent of children under age five in Sudan were moderately or severely stunted (too short for their age) (Table 5.1). There was some difference in terms of those who were severely and moderately stunted among boys (37.4 per cent) and girls (32.6 per cent). The proportion of moderately or severely stunted children was higher in rural areas (38.7 per cent) than in urban areas (25.3 per cent). The percentage of children classified as moderately or severely stunted decreases with increasing levels of education of the mother. For instance, the percentage of moderately stunted children was 40.0 for children of mothers with no formal education, 31.4 for children of mothers with primary education, and 22.9 among children of mothers with secondary or higher levels of education. The percentage of moderately or severely stunted children also decreases with increasing levels of economic status of the households. The percentage of moderately or severely stunted children was 42.1 among children from households in the poorest quintile compared to 15.0 among children belonging to households in

the richest quintile. The proportion of children who were moderately or severely stunted was the lowest in Khartoum State (21.9 per cent) and the highest in Red Sea State (Table 5.1 and Figure 5.3).

Stunting prevalence (Severe): The SHHS2 findings indicated that about 15.7 per cent of children under age five in Sudan were severely stunted (Table 5.1). There was some difference between boys (17.3 per cent) and girls (14.0 per cent) in terms of those who were severely stunted. The proportion of severely stunted children was higher in rural areas (18.0 per cent) than in urban areas (9.5 per cent). The percentage of severely stunted children decreases with increasing levels of education of the mother. For instance, the percentage of severely stunted children was 18.8 among children of mothers with no formal education, 13.1 among children of mothers with primary education, and 9.0 among children of mothers with secondary or higher levels of education. The percentage of children classified as severely stunted also decreases with increasing economic status of the households. The percentage of severely stunted children was 18.6 among those from households in the poorest quintile compared to 5.2 among children belonging to households in the richest quintile.

The proportion of children who were severely stunted was lowest in Khartoum (7.8 per cent) and the highest in Red Sea State (30.6 per cent). (Table 5.1 and Figure 5.1B).

Wasting prevalence

Wasting prevalence (moderate and severe): Approximately one out of six under-five children (16.4 per cent) in Sudan were found to be moderately or severely wasted (too thin for their height) (Table 5.1). Wasting is usually the result of a recent nutritional deficiency related to, for example, recent illness or inadequate diet intake. The prevalence estimate may exhibit significant seasonal shifts associated with changes in the availability of food or disease prevalence. There was some difference in terms of those who were moderately or severely wasted among boys (17.9 per cent) and girls (14.8

per cent). The proportion of moderately or severely wasted children was higher in rural areas (17.3 per cent) than in urban areas (14.0 per cent). The percentage of moderately or severely wasted children was found to decrease with increasing levels of education of the mother. For instance, the percentage of moderately or severely wasted children was 17.4 among children of mothers with no formal education, compared to 15.6 among children of mothers with primary education, and 14.1 among children of mothers with secondary or higher levels of education. The percentage of moderately or severely wasted children also decreases with increasing levels of economic status of the households. The percentage of moderately or severely wasted children was 18.8 among children from households in the poorest quintile compared to 12.7 among children belonging to households in the richest quintile. The proportion of children who were moderately or severely wasted was lowest in Khartoum State (12.8 per cent) and the highest in Red Sea State (28.5 per cent) (Table 5.1 and Figure 5.4).

Wasting prevalence (Severe): Approximately 5.3 per cent of under-five children in Sudan was found to be severely wasted (Table 5.1). There was a difference in terms of those who were severely wasted among boys (5.9 per cent) and girls (4.6 per cent). The proportion of severely wasted children was higher in rural areas (5.6.0 per cent) than in urban areas (4.4 per cent). The percentage of severely wasted children was found to decrease with increasing levels of education of the mother. For instance, the percentage of severely wasted children was 5.9 among children of mothers with no formal education, 4.7 among children of mothers with primary education, and 4.0 among children of mothers with secondary or higher levels of education. The percentage of severely wasted children also decreases with increasing levels of economic status of the households. The percentage of severely wasted children was 5.9 among children from households in the poorest quintile compared to 3.8 for children belonging to households in the richest quintile. The proportion of children who were severely wasted was highest in Red Sea State (14.7 per cent) and the lowest in Khartoum (3.9 per cent). (Table 5.1).

Overweight prevalence

The SHHS2 findings indicated that about 2.9 per cent of under-five children were found to be overweight (Table 5.1) with more boys (3.2 per cent) overweight than girls (2.5 per cent). The percentage of children classified as overweight was highest in Red Sea State (6.2 per cent) and the lowest in Khartoum State (2.2 per cent).

Nutritional status by age group

The SHHS2 data (Table 5.1) indicates that the underweight, stunting, and wasting prevalence among under-five children varies with age. The age pattern shows that the underweight prevalence (moderate and severe) was higher among children aged 12-23 months (36.2 per cent) than among those aged 0-5 months (27.2 per cent), 6-11 months (27.0 per cent), 24-35 months (35.4 per cent), 36-47 months (31.6 per cent) and those aged 48-59 months (30.7 per cent). The underweight prevalence (severe) was higher among children aged 24-35 months (14.4 per cent) than those aged 0-5 months (17.5 per cent), 6-11 months (9.7 per cent), 12-23 months (12.9 per cent), 36-47 months (11.2 per cent) and those aged 48-59 months (9.9 per cent).

The stunting prevalence (moderate or severe) was higher among children aged 24-35 months than those aged 0-5 months (16.9 per cent), 6-11 months (20.3 per cent), 12-23 months (38.9 per cent), 36-47 months (40.5 per cent) and those aged 48-59 months (33.4 per cent). The stunting prevalence (severe) was higher among children aged 24-35 months (21.1 per cent) than among those aged 0-5 months (8.5 per cent), 6-11 months (6.4 per cent), 12-23 months (17.2 per cent), 36-47 months (17.2 per cent) and those aged 48-59 months (15.4 per cent).

The wasting prevalence (moderate and severe) was higher among children aged 12-23 months (20.6 per cent) than among those aged 0-5 months (17.6 per cent), 6-11 months (19.9 per cent), 24-35 months (15.4 per cent), 36-47 months (13.1 per cent) and those aged 48-59 months (13.7 per cent). The wasting prevalence (severe) was also higher among children aged 0-5 months (7.6 per cent) than among those aged 6-11 months (5.0 per cent), 12-23 months (6.7 per cent), 24-35 months (4.7 per cent), 36-47 months (4.4 per cent) and those aged 48-59 months (4.1 per cent).

Figure 5.5 presents the status in relation to the proportion of under-five children who were severely underweight, stunted, wasted by different age groups. The figure shows that severe underweight peaks in the age group 24-35 months (14.4 per cent). Severe stunting peaks in the age group 24-35 months (21.1 per cent) while severe wasting peaks in the age category of 0-5 months (7.6 per cent).

Breastfeeding and Infant and Young Child Feeding

Breast feeding

Breastfeeding for the first few years of life protects children from infection, provides an ideal source of nutrients, and is economical and safe. However, many mothers stop breastfeeding too soon and there are often pressures to switch to infant formula, which can contribute to growth faltering and micronutrient malnutrition and is unsafe if clean water is not readily available.

WHO/UNICEF have the following feeding recommendations:

- Exclusive breastfeeding for first six months;
- Continued breastfeeding for two years or more;
- Safe, appropriate and adequate complementary foods beginning at 6 months;
- Frequency of complementary feeding: 2 times per day for 6-8 month olds; 3 times per day for 9-11 month olds;

It is also recommended that breastfeeding be initiated within one hour of birth.

- *Minimum meal frequency (6-23 months)*: Proportion of infants aged 0-11 months who are appropriately fed: i.e., proportion of infants aged 0-5 months who are exclusively breastfed and proportion of infants aged 6-11 months who are breastfed and ate solid or semi-solid food at least the minimum recommended number of times (two times per day for infants aged 6-8 months, three times per day for infants aged 9-11 months) on the previous day;
- *Milk feeding frequency for non-breastfeeding children (6-23 months)*: Proportion of non-breastfed children age 6-23 months who received at least 2 milk feedings during the previous day;
- *Bottle feeding (0-23 months)*: Proportion children age 6-23 months who were fed with a bottle during the previous day;

Early initiation of breastfeeding

Table 5.3 provides the proportion of children born in the last two years who were ever breastfed, and those who were first breastfed within one hour and one day of birth. Although a very important step in management of lactation and establishment of a physical and emotional relationship between the baby and the mother, only 73.2 per cent of babies were found to have been breastfed for the first time within one hour of birth, while 92.6 per cent of newborns in Sudan started breastfeeding within one day of birth.

The percentage of babies who were breastfed for the first time within one hour of birth ranged between 87.3 in Kassala State and 63.0 in West Darfur State. The percentage of infants who were first breastfed within one day of birth ranged between 99.2 in Northern State and 76.4 in West Darfur State.

The SHHS2 findings indicate that the percentage of babies who were breastfed for the first time within one hour and one day of birth increases with the increasing level of mother's education. For instance, the percentage of babies who were breastfed for the first time within one hour of birth was 71.7 for babies who had mothers with no formal education compared to 77.4 for babies who had mothers with secondary or higher level of education. The percentage of babies who were breastfed for the first time within one day of birth was 91.4 for babies who had mothers with no formal education compared to 96.4 for babies who had mothers with secondary or higher level of education.

Background characteristics	Percentage ever breastfed [1]	Percentage who were first breastfed: Within one hour of birth [2]	Percentage who were first breastfed: Within one day of birth	Number of children born in the two years preceding the survey

[1] SHHS indicator 2.4				
[2] SHHS indicator 2.5				

The percentage of babies who were breastfed for the first time within one hour of birth or within one day of birth varied between babies belonging to the poorest and richest households. For instance, the percentage of babies who were breastfed for the first time within one hour of birth was 70.4 among babies of mothers belonging to the poorest households as compared to 72.5 among babies of mothers belonging to the richest households. Similarly, the percentage of babies who were breastfed for the first time within one day of birth was 89.6 among babies of mothers belonging to the poorest households compared to 97.1 among children of mothers belonging to the richest households.

Breastfeeding status by age group

Table 5.4 presents breastfeeding status at selected age groups. The breastfeeding status is based on the reports of mothers/caretakers of children's consumption of food and fluids in the 24 hours prior to the interview. *Exclusively breastfed* refers to infants who received only breast milk (and vitamins, mineral supplements, or medicine). The table shows exclusive breastfeeding of infants during the first six months of life, as well as continued breastfeeding of children at 12-15 and 20-23 months of age.

Predominant breastfeeding under six months: The SHHS2 data indicated that about four in five (79.8 per cent) infants aged 0-5 months were predominantly breastfed (Table 5.4). The percentage of children aged 0-5 months who were predominantly breastfed was higher among children in rural areas (81.9 per cent) than those in urban areas (73.8 per cent). The percentage of children aged 0-5 months who were predominantly breastfed declined from 80.5 for children of mothers with no education to 73.2 for children with mothers with secondary or higher level of education. The percentage of children aged 0-5 months who were predominantly breastfed also declined from 86.0 among children belonging to households in the poorest quintile to 69.9 among children belonging to households in the richest quintile. The percentage of children age 0-5 months who were predominantly breastfed ranged between 62.5 in Northern State and 88.0 in South Darfur State.

Continued breastfeeding rate at one year: The SHHS2 data indicated that about 87.6 per cent of children age 12-15 months received continued breastfeeding at one year. The percentage of children age 12-15 months who received continued breastfeeding was higher in urban areas (90.8 per cent) than that of children in rural areas (86.3 per cent). The percentage of children aged 12-15 months who received continued breastfeeding at one year was 87.0 for children of mothers with no education compared to 88.6 for children of mothers with primary education and 87.6 for children of mothers with secondary or higher level of education. The percentage of children aged 12-15 months who received continued breastfeeding at one year was 87.2 for children belonging to households in the poorest quintile compared to 91.0 for children belonging to households in the richest quintile. The percentage of children age 12-15 months who received continued breastfeeding at one year ranged between 98.0 in Northern State and 78.3 in West Darfur State.

Continued breastfeeding rate at two years: The SHHS2 data also indicated that about 40.1 per cent of children age 20-23 months received continued breastfeeding at two years. Girls aged 20-23 months were more likely to be breastfed (continued breastfeeding at 2 years) than boys. The percentage of girls age 20-23 months who received continued breastfeeding was 43.2 per cent as compared to 37.4 per cent for boys age 20-23 months. There was also some difference in the

percentage of children aged 20-23 months in urban areas (38.6 per cent) and rural areas (40.6 per cent) who received continued breastfeeding at two years. The percentage of children age 20-23 months who received continued breastfeeding at two years was 40.7 per cent for children of mothers with no education, compared to 37.0 for children of mothers with primary education and 47.5 per cent for children of mothers with secondary or higher level of education. The percentage of children age 20-23 months who received continued breastfeeding at two years was 47.3 for children belonging to households in the poorest quintile compared to 34.0 for children belonging to households in the richest quintile. The percentage of children age 20-23 months who received continued breastfeeding at two years ranged between 64.4 in Northern State and 23.4 in West Darfur State.

The SHHS2 findings indicated that about 65.0 per cent of 0-1 month old children were exclusively breastfed in North Sudan. Even at the earliest ages, a large proportion of children were receiving liquids or foods other than breast milk. Among children who were 2-3 months, the percentage of children that were exclusively breastfed declined to 49.9 per cent while about 47.6 per cent received liquids or foods along with breastfeeding. About 2.5 per cent of children aged 2-3 months were weaned (not breastfed). The percentage of children that were exclusively breastfed was only 18.3 per cent among children aged 4-5 months, though exclusive breastfeeding is considered as adequate feeding up to six months. Few mothers continued breastfeeding up to 23 months. In all, only about 29.4 percent of children aged 22-23 months were receiving breast milk (Figure 5.8)

Duration of breastfeeding

Table 5.6 shows the median duration of breastfeeding by selected background characteristics. Among children under age 3, the median duration was 20.2 months for any breastfeeding, 1.8 months for exclusive breastfeeding, and 5.4 months for predominant breastfeeding. The mean for all children in the age group 0-35 months was 18.9 months for any breastfeeding, 2.6 months for exclusive breastfeeding, and 6.2 months for predominant breastfeeding.

Median duration (in months) of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children age 0-35 months, 2010				
Background characteristics	Median duration (in months) of			Number of children age 0-35 months
	Any breastfeeding [1]	Exclusive breastfeeding	Predominant breastfeeding	

Sex				
Male	20.0	1.6	5.3	4222
Female	20.4	1.9	5.5	4117
Area of residence				
Urban	20.3	1.7	4.8	2309
Rural	20.2	1.8	5.6	6031
Mother's education level

Mean for all children (0-35 months)	18.9	2.6	6.2	8339
[1] SHHS indicator 2.10				

Among male children under age 3, the median duration was 20.0 months for any breastfeeding, 1.6 months for exclusive breastfeeding, and 5.3 months for predominant breastfeeding, while among female children under age 3, the median duration was 20.4 months for any breastfeeding, 1.9 months for exclusive breastfeeding, and 5.5 months for predominant breastfeeding. Among children under age 3 in urban areas, the median duration was 20.3 months for any breastfeeding, 1.7 months for exclusive breastfeeding, and 4.8 months for predominant breastfeeding, while among children under age 3 in rural areas, the median duration was 20.2 months for any breastfeeding, 1.8 months for exclusive breastfeeding, and 5.6 months for predominant breastfeeding.

There was very little impact of educational status of mothers on the duration of breast feeding. Among children (under age 3) of mothers with no education, the median duration was 20.2 months for any breastfeeding, 1.4 months for exclusive breastfeeding, and 5.7 months for predominant breastfeeding, while among children (under age 3) of mothers with secondary education or more, the median duration was 20.7 months for any breastfeeding, 2.3 months for exclusive breastfeeding, and 4.5 months for predominant breastfeeding. Among children (under age 3) belonging to the poorest households, the median duration was 20.7 months for any breastfeeding, 1.7 months for exclusive

[1] SHHS indicator 2.6						
[2] SHHS indicator 2.14						

The proportion of adequately fed children aged 0-5 months varied between children of mothers with no education and children of mothers with secondary and higher level of education. The SHHS data indicated that proportion of adequately fed children aged 0-5 was only 37.7 per cent who had mothers with no education compared to 43.7 per cent among children who had mothers with secondary education or higher level of education. The SHHS data also indicated that there was some difference in the proportion of adequately fed children (aged 0-5 months) between children from the poorest and richest households. About 43.7 per cent of children (aged 0-5 months) belonging to the richest households were adequately fed compared to 40.7 per cent of children from the poorest households. The percentage of children age 0-5 months that were being adequately fed ranged between 70.3 per cent in North Darfur State and 32.4 per cent in White Nile State (Table 5.7).

The SHHS findings indicated that according to the feeding patterns, only 52.6 percent of children aged 6-23 months were being adequately fed at the time of the SHHS. There was no difference between male and female children aged 6-23 months in terms of adequacy of feeding the proportion of male and female children adequately fed being 52.7 per cent and 52.6 per cent respectively. There was, however, a significant difference between children aged 6-23 months in rural and urban areas in terms of adequacy of feeding, the proportion of male and female children exclusively breastfed being 59.4 per cent and 50.0 per cent respectively. The proportion of adequately fed children aged 6-23 months varied between children of mothers with no education and children of mothers with secondary and higher level of education. The SHHS data indicated that proportion of adequately fed children aged 6-23 months was only 49.6 per cent who had mothers with no education compared to 60.1 per cent among children who had mothers with secondary or higher level of education. The SHHS data also indicated that there was some difference in the proportion of adequately fed children (aged 6-23 months) between children from the poorest and richest households. About 56.2 per cent of children (aged 6-23 months) belonging to the richest households were adequately fed compared to 46.4 per cent of children from the poorest households. The percentage of children aged 6-23 months who were being adequately fed ranged between 69.1 per cent in Northern State and 24.0 per cent in West Darfur State.

The SHHS findings also indicated that according to the feeding patterns, only 49.4 per cent of children aged 0-23 months were being appropriately breastfed. There was no difference between male and female children aged 0-23 months who were appropriately breastfed, the proportion of male and female children appropriately breastfed being 49.3 per cent and 49.5 per cent respectively. There was, however, a significant difference between children aged 0-23 months in rural (47.5 per cent) and urban areas (54.4 per cent) who were appropriately breastfed. The proportion of appropriately breastfed children aged 6-23 months varied between children of mothers with no education and children of mothers with secondary and higher level of education. The SHHS data indicated that proportion of appropriately breastfed fed children aged 6-23 months was only 46.2 per cent who had mothers with no education compared to 56.8 per cent among children who had mothers with secondary or higher level of education. There was some difference in the proportion of appropriately breastfed children (aged 0-23 months) between children from the poorest and richest households. About 53.0 per cent of children belonging to the richest households were adequately fed compared to 44.8 per cent of children from the poorest households. The percentage of children aged 0-23 months who were being appropriately breastfed ranged between 59.3 per cent in Northern State and 31.1 per cent in West Darfur State (Table 5.7 and Figure 5.10)

Complementary feeding

Adequate complementary feeding of children from 6 months to two years of age is particularly important for growth and development and the prevention of under nutrition. Continued breastfeeding beyond six months should be accompanied by consumption of nutritionally adequate, safe and appropriate complementary foods that help meet nutritional requirements when breast milk is no longer sufficient. This requires that for breastfed children, two or more meals of solid, semi-solid or soft foods are needed if they are six to eight months old, and three or more meals if they are 9-23 months of age. For children 6-23 months and older who are not breastfed, four or more meals of solid, semi-solid or soft foods or milk feeds are needed.

Table 5.8 indicates information related to the introduction of solid, semi-solid or soft food. Overall, 51.1 percent of children aged 6-8 months received solid, semi-solid, or soft foods. Among currently breastfeeding children, this percentage was 51.5 while it was 22.2 among children currently not breastfeeding.

**Table 5.8: Introduction of solid, semi-solid or soft food
Percentage of infants age 6-8 months who received solid, semi-solid or soft foods during
the previous day, Sudan, 2010**

	Currently breastfeeding		Currently not breastfeeding	All	
	Percent receiving solid, semi- solid or soft foods	Number of children age 6-8 months	Number of children age 6-8 months	Percent receiving solid, semi- solid or soft foods [1]	Number of children age 6-8 months
Sex					
Male	56.4	348	7	55.7	360
Female	46.9	363	3	46.5	369
Area of residence					
Urban	59.9	185	6	58.6	191
Rural	48.6	526	4	48.4	538
SUDAN (TOTAL)	51.5	711	10	51.1	729

Overall, 55.7 per cent of male children aged 6-8 months and 46.5 per cent of female children received solid, semi-solid, or soft foods, while of the total number of children aged 6-8 months surveyed in urban and rural areas, 58.6 per cent of children in urban areas and 48.4 per cent of children in rural areas received solid, semi-solid, or soft foods. The percentage of male children aged 6-8 months currently breastfeeding and receiving solid, semi-solid or soft foods was 56.4 as compared to 46.9 for female children. This percentage for male children currently not breastfeeding was 24.6 compared to 16.6 for female children. The percentage of children aged 6-8 months in urban areas currently breastfeeding and receiving solid, semi-solid or soft foods was 59.9 compared to 48.6 for children in rural areas. The percentage of children in urban areas currently not breastfeeding and receiving solid, semi-solid or soft foods was 18.0 compared to 28.2 for children in rural areas.

Minimum meal frequency

Table 5.9 presents the minimum meal frequency of children aged 6-23 months, i.e. proportion of children aged 6-23 months who received solid, semi-solid or soft foods (and milk feeds for non-breastfeeding children) the minimum number of times or more during the previous day, according to breastfeeding status.

Among currently breastfeeding children aged 6-23 months, nearly one-fourth (24.9 per cent) of them had the minimum meal frequency and were receiving solid, semi-solid and soft foods the minimum number of times and this proportion was slightly higher among females (25.1 per cent) than among males (24.7 per cent). A higher proportion of currently breastfeeding children aged 6-23 months in urban areas (27.6 per cent) were enjoying the minimum meal frequency compared to children in rural areas (23.8 per cent).

The proportion of currently breastfeeding children aged 6-23 months who received solid, semi-solid and soft foods the minimum number of times varied between children belonging to the poorest and richest households. While only 20.1 per cent of currently breastfeeding children aged 6-23 months belonging to the poorest households received solid, semi-solid and soft foods the minimum number of times, this percentage was higher (26.5 per cent) among children belonging to the richest households. The proportion of currently breastfeeding children aged 6-23 months who received solid, semi-solid and soft foods the minimum number of times ranged between 42.2 per cent in Blue Nile State and 14.5 per cent in Red Sea State.

The SHHS data indicated that among children aged 6-23 months currently not breastfeeding, nearly half (50.5 per cent) of them received solid, semi-solid and soft foods or milk feeds 4 times or more a day. This proportion was higher among female children (52.4 per cent) than among male children (49.0 per cent). A higher proportion of currently not breastfeeding children in urban areas (57.2 per cent) received solid, semi-solid and soft foods or milk feeds 4 times or more a day compared to children in rural areas (48.2 per cent). The proportion of currently not breastfeeding children aged 6-23 months who received solid, semi-solid and soft foods or milk feeds 4 times or more a day varied between children belonging to the poorest and richest households. While only 47.0 per cent of currently not breastfeeding children aged 6-23 months from the poorest households received solid, semi-solid and soft foods or milk feeds 4 times or more a day, this percentage was significantly higher (63.4 per cent) among children belonging to the richest households. The SHHS findings also indicated that mother's education level had an influence on the proportion of children aged 6-23 months currently not breastfeeding who received solid, semi-solid and soft foods or milk feeds 4 times or more. The proportion of children aged 6-23 months currently not breastfeeding who received solid, semi-solid and soft foods or milk feeds 4 times or more was only 47.0 per cent among children of mothers who had no education compared to 59.7 per cent among children of mothers who had secondary or higher level of education.

The SHHS data also indicated that among children aged 6-23 months currently not breastfeeding, more than half (55.8 per cent) of them received at least two milk feeds a day. This percentage was slightly higher among female children (56.4 per cent) than among male children (55.3 per cent). A higher proportion of currently not breastfeeding children in urban areas (58.3 per cent) received at least two milk feeds a day compared to children in rural areas (54.9 per cent). The proportion of children aged 6-23 months currently not breastfeeding and who received at least two milk feeds a day ranged between 73.3 per cent in White Nile State and 38.4 per cent in North Kordofan State (Table NU.6). The SHHS findings also indicated that the proportion of children aged 6-23 months currently not breastfeeding and received at least two milk feeds a day varied between children belonging to the poorest and richest households. While only 47.0 per cent of the children aged 6-23 months (currently not breastfeeding) belonging to the poorest households received at least two milk feeds a day, this proportion was quite higher (73.6 per cent) among children belonging to the richest households.

Table 5.9 also provides information on the percentage of children aged 6-23 months who enjoyed the minimum meal frequency. Overall, less than one-third (30.3 per cent) of the children age 6-23 months enjoyed the minimum meal frequency. A slightly higher proportion of females (30.4 per cent) enjoyed the minimum meal frequency compared to males (30.1 per cent). A higher proportion of children aged 6-23 months in urban areas (33.4 per cent) enjoyed the minimum meal frequency compared to children in rural areas (29.0 per cent). Similarly, of all children aged 6-23 months, while 33.9 per cent of them belonging to the richest households enjoyed the minimum meal frequency, this proportion was only 24.0 per cent in the case of children belonging to the poorest households.

The proportion of children aged 6-23 months who enjoyed the minimum meal frequency ranged between 49.6 per cent in Gedarif State and 19.6 per cent in North Darfur State. (Table 5.9 and Figure 5.11).

Figure 5.11: Minimum meal frequency (Percentage of children age 6-23 months who received solid, semi-solid, or soft foods (and milk feeds for non-breastfeeding children) the minimum number of times or more during the previous day of SHHS2), Sudan, 2010

Bottle feeding

Table 5.10 indicates the percentage of children age 0-23 months that were fed with a bottle with a nipple during the previous day of the SHHS. The continued practice of bottle-feeding is a concern because of the possible contamination due to unsafe water and lack of hygiene in preparation. The practice of bottle feeding tends to substitute breastfeeding resulting in adverse effects on the child, such as diarrheal diseases.

Table 5.10 shows that bottle-feeding is still prevalent in North Sudan. The SHHS findings indicate that 5.1 percent of children aged 0-23 months were fed using a bottle with a nipple on the previous day of the SHHS. The percentage of children aged 0-23 months that were fed with a bottle with a nipple was slightly higher for male children (5.6 per cent) than that for female children (4.5 per cent). Similarly, the percentage of children aged 0-23 months that were fed with a bottle with a nipple was higher for children in urban areas (10.7 per cent) than for children in rural areas (3.0 per cent). The percentage of children aged 0-23 months that were fed with a bottle with a nipple decreased from 7.4 per cent in the case of children aged 0-5 months to 5.5 per cent in the case of children aged 6-11 months and to 3.5 per cent in the case of children aged 12-23 months.

The percentage of children age 0-23 months that were fed with a bottle with a nipple showed an increasing trend with the level of mother's educational status and the economic status of the households. The percentage of children that were fed with a bottle with a nipple was only 4.5 per cent for children of mothers with no education compared to 8.5 per cent for children with mothers with

secondary or higher level of education. Similarly, the percentage of children aged 0-23 months that were fed with a bottle with a nipple was only 0.8 per cent for children from the poorest households compared to 15.3 per cent for children from the richest households.

Table 5.10: Bottle feeding
Percentage of children age 0-23 months who were fed with a bottle with a nipple during the previous day, Sudan, 2010

The percentage of children aged 0-23 months that were fed with a bottle with a nipple ranged from 0.5 per cent in Blue Nile state to 15.2 per cent in Khartoum state.

Micronutrients

While data is limited, available information suggests that the micronutrient status of the population in Sudan is unsatisfactory. Localised surveys have reported night blindness in some parts of Sudan, due

iodized salt production from the main sources was initiated to cover 100 per cent of households and the banning of production of non-iodized salt after a six-month grace period. The machines and materials (including potassium iodate) required for the production of iodized salt have already been procured and iodized salt production commenced in June 2007.

Table 5.11 shows that in a very small proportion of households (2.4 per cent), there was no salt available at the time of the survey. The SHHS2 findings indicated that only a very small proportion of households (14.7 per cent) were found to be using iodized salt. In only 9.5 per cent of households, salt was found to contain 15 parts per million (ppm) or more of iodine, while in the case of 5.3 per cent of households, salt was found to contain less than the required 15 parts per million (ppm). About 10.5 per cent of urban households were found to be consuming adequately iodized salt as compared to 9.1 per cent in rural areas. Interestingly, the consumption of adequately iodised salt was higher among the poorest households (17.9 per cent) than among the richest households (6.5 per cent).

Consumption of adequately iodized salt was lowest in Blue Nile State (0.8 per cent) and highest in South Darfur State (66.6 per cent). (Table 5.11 and Figure 5.12).

Children's Vitamin A Supplementation

Vitamin A is essential for eye health and proper functioning of the immune system. It is found in foods such as milk, liver, eggs, red and orange fruits, red palm oil and green leafy vegetables, although the amount of vitamin A readily available to the body from these sources varies widely. In developing areas of the world, where Vitamin A is largely consumed in the form of fruits and vegetables, daily per capita intake is often insufficient to meet dietary requirements. Inadequate intakes are further compromised by increased requirements for the vitamin as children grow or during periods of illness, as well as increased losses during common childhood infections. As a result, Vitamin A deficiency is quite prevalent in the developing world and particularly in countries with the highest burden of under-five deaths.

The 1990 World Summit for Children set the goal of virtual elimination of Vitamin A deficiency and its consequences, including blindness, by the year 2000. This goal was also endorsed at the Policy Conference on Ending Hidden Hunger in 1991, the 1992 International Conference on Nutrition, and the UN General Assembly's Special Session on Children in 2002. The critical role of Vitamin A for child health and immune function also makes control of deficiency a primary component of child survival efforts, and therefore critical to the achievement of the fourth Millennium Development Goal: a two-thirds reduction in under-five mortality by the year 2015.

For countries with Vitamin A deficiency problems, current international recommendations call for high-dose Vitamin A supplementation every four to six months, targeted to all children between the ages of six to 59 months living in affected areas. Providing young children with two high-dose Vitamin A capsules a year is a safe, cost-effective, efficient strategy for eliminating Vitamin A deficiency and improving child survival. Giving Vitamin A to new mothers who are breastfeeding helps protect their children during the first months of life and helps to replenish the mother's stores of Vitamin A, which are depleted during pregnancy and lactation. For countries with Vitamin A supplementation programs, the definition of the indicator is the percent of children 6-59 months of age receiving at least one high dose Vitamin A supplement in the last six months.

Based on UNICEF/WHO guidelines, the Federal Ministry of Health recommends that children aged 6-11 months be given a high dose Vitamin A capsules every six months. Since 2007, Vitamin A capsule supplementation has been provided to children aged 6-11 months in Sudan as a part of the child health week (previously referred to as ACSD which stands for accelerated child survival days) organised on a six-monthly basis as part of the strategy adopted by the Federal Ministry of Health to reduce vitamin A deficiency among children. It is also recommended that mothers take a Vitamin A supplement within six weeks of giving birth due to increased Vitamin A requirements during lactation and replete loss during pregnancy.

Table 5.12 indicates the percent distribution of children aged 6-23 months who received Vitamin A during the last six months preceding the SHHS. Within the six months prior to the SHHS, 60.5 percent of children aged 6-23 months received a high dose Vitamin A supplement. The percentage of children aged 6-23 months that received a high dose Vitamin A supplement was slightly higher for male children (61.2 per cent) than that for female children (59.7 per cent). Similarly, the percentage of children aged 6-23 months that received a high dose Vitamin A supplement was slightly higher for children in urban areas (60.7 per cent) than that for children in rural areas (60.4 per cent).

The SHHS findings indicate that the mother's level of education has an influence on the likelihood of Vitamin A supplementation. The percentage of children aged 6-23 months who received a Vitamin A supplement in the last six months increases from 55.8 percent among children whose mothers had no education to 64.5 percent of those whose mothers have primary education and 69.2 percent among children of mothers with secondary or higher levels of education. The economic status of the household was found to have some influence on the likelihood of Vitamin A supplementation. The percentage of children aged 6-23 months who received Vitamin A supplement in the last six months showed an increasing trend from 50.1 percent among children from the poorest households to 66.2 percent among children from the richest households.

[1] SHHS indicator 2.17 Results are based on mother's report		

Vitamin A supplementation coverage ranged from 31.7 per cent in West Darfur State and 34.9 per cent in Red Sea State to 77.3 in White Nile state and 82.6 per cent in Blue Nile State (Table 5.12 and Figure 5.13)

Post-partum Mother's Vitamin A Supplementation

Table 5.13 indicates the status relating to post-partum mother's Vitamin A supplementation. It shows the percentage of women aged 15-49 years with a birth in the last two years preceding the SHHS2 whether they received a high dose Vitamin A supplement.

The SHHS2 findings indicate that about 22.1 per cent of women aged 15-49 years with a birth in the 2 last years preceding the SHHS received Vitamin A supplement. The percentage of women that received Vitamin A supplement was higher in urban areas (31.3 per cent) than that for women in rural areas (18.6 per cent).

The SHHS2 data indicates that the woman's level of education is related to the likelihood of Vitamin A supplementation for women aged 15-49 years with a birth in the 2 last years preceding the SHHS. The percentage of women aged 15-49 years with a birth in the 2 last years who received Vitamin A supplement showed an increasing trend from 16.9 per cent among women who had no education to 24.9 per cent among women who had primary education and 32.0 per cent among women who had secondary or higher level of education. The economic status of the households is also related to the likelihood of Vitamin A supplementation. The percentage of women aged 15-49 years with a birth in the 2 last years preceding the SHHS who received Vitamin A supplement increased from 11.0 per cent among women belonging to the poorest households to 34.1 per cent among women belonging to the richest households.

Table 5.13: Post-partum mother's Vitamin A supplementation (NU10M)

Vitamin A supplementation coverage among women aged 15-49 years with a birth in the 2 last years preceding the SHHS ranged from 10.3 per cent in South Darfur State to 46.7 per cent in Khartoum State. The National Nutrition Policy (2008) includes a strategy to improve maternal nutrition status, specifying working with Reproductive Health Section of FMOH and other partners to increase availability and access to existing antenatal and postnatal care, including iron/folate and vitamin A supplementation. Accordingly, Vitamin A is administered to post-partum women at their first post-natal contact with a health facility.

quintile (21) and those from households in the richest quintile (23). The percentage of severely anaemic women was lower among pregnant women (14 per cent) than women who were not pregnant (24 per cent) at the time of the SHH2. The proportion of women age 15-49 years who were severely anaemic ranged from 13 per cent in West Darfur to 38 per cent in Gadarif State (Table 5.15).

**Table 5.15: Prevalence of anaemia among women age 15-49 years
Proportion of women age 15-49 years who were found to be anaemic at the time of the SHHS2,
Sudan, 2010**

VI. Child Health

Vaccinations

The Millennium Development Goal (MDG) 4 is to reduce child mortality by two thirds between 1990 and 2015. Immunization plays a key part in this goal. Immunizations have saved the lives of millions of children in the three decades since the launch of the Expanded Programme on Immunization (EPI) in 1974. Worldwide there are still 27 million children overlooked by routine immunization and as a result, vaccine-preventable diseases cause more than 2 million deaths every year.

A World Fit for Children goal is to ensure full immunization of children under one year of age at 90 percent nationally, with at least 80 percent coverage in every district or equivalent administrative unit.

According to UNICEF and WHO guidelines, a child should receive a Bacillus-Cereus-Geuerin (BCG) vaccination to protect against tuberculosis, three doses of DPT to protect against diphtheria, pertussis, and tetanus, three doses of polio vaccine, and a measles vaccination by the age of 12 months.

During the SHHS2, mothers were asked to provide vaccination cards for children under the age of five. Interviewers copied vaccination information from the cards onto the SHHS questionnaire. If the child did not have a card, the mother was asked to recall whether or not the child had received each of the vaccinations and, for DPT and Polio, how many times. Overall, 40.6 per cent of children had health cards (Table 6.2).

Table 6.1 indicates the percentage of children aged 12 to 23 months who received each of the vaccinations. The denominator for the table is comprised of children age 12-23 months so that only children who are old enough to be fully vaccinated are counted. In the top panel, the numerator includes all children who were vaccinated at any time before the survey according to the vaccination card or the mother's report. In the bottom panel, only those who were vaccinated before their first birthday, as recommended, are included. For children without vaccination cards, the proportion of vaccinations given before the first birthday is assumed to be the same as for children with vaccination cards.

	Vaccinated at any time before the survey according to: Vaccination card	Vaccinated at any time before the survey according to: Mother's report	Vaccinated at any time before the survey according to: Either	Vaccinated by 12 months of age
BCG [1]	39.4	37.4	76.8	74.6
Polio 0	26.1	15.3	41.4	40.2
Polio 1	40.3	45.9	86.2	83.3
Polio 2	38.5	41.8	80.3	77.4
Polio 3 [2]	37.0	27.8	64.8	62.0
DPT HB HIB 1	40.5	38.2	78.7	74.8
DPT HB HIB 2	38.7	32.4	71.1	68.3
DPT HB HIB 3 [3]	37.3	24.0	61.3	58.4
Measles [4]	37.6	32.5	70.1	62.3
All vaccinations	35.5	13.9	49.4	39.3
No vaccinations	.0	8.0	8.0	8.8
Number of children age 12-23 months	2612	2612	2612	2612
[1] SHHS indicator 3.1 [2] SHHS indicator 3.2 [3] SHHS indicator 3.3 [4] SHHS indicator 3.4; MDG indicator 4.3				

Approximately 74.6 per cent of children age 12-23 months received BCG vaccination by 12 months of age. The first dose of DPT HB HIB was given to 74.8 per cent. The percentage declined for subsequent doses of DPT HB HIB to 68.3 per cent for the second dose, and 58.4 per cent for the third dose (Figure 6.1). Similarly, 83.3 per cent of children received Polio 1 by 12 months of age and this declined to 77.4 per cent for the second dose and 62.0 per cent by the third dose. The coverage for measles vaccine by 12 months of age was lower than for the other vaccines at 62.3 per cent. This is primarily because, although 70.1 per cent of children received the vaccine, only 62.3 per cent received it by their first birthday. As a result, the percentage of children who had all the recommended vaccinations by their first birthday was low at only 39.3 per cent. Important to mention that approx. 9 per cent of children had not received any vaccinations i.e have not been reached by health services

Table CH.2 shows vaccination coverage rates among children 12-23 months by background characteristics. The Table indicates the percentage of children age 12-23 months vaccinated against childhood diseases at any time up to the date of the survey. The figures are based on information from both the vaccination cards and mothers/caretakers' reports.

Table 6.2: Vaccinations by background characteristics													
Percentage of children age 12-23 months currently vaccinated against childhood diseases, Sudan, 2010													
Richest	91.6	64.6	90.9	88.9	73.3	93.0	90.8	86.3	92.2	1.7	67.9	51.0	363
SUDAN (TOTAL)	76.8	41.4	86.2	80.3	64.8	78.7	71.1	61.3	70.1	8.0	49.4	40.6	2612

Major state differentials exist in regard to the percentage of children aged 12-23 months who received BCG, Polio, DPT, and measles vaccinations at any time up to the date of the survey.

Tuberculosis immunisation coverage: The SHHS2 data indicated that 76.8 per cent of children age 12-23 months had received BCG vaccination at any time up to the date of the survey. There was only a slight difference in BCG vaccination coverage rate by gender, the BCG vaccination coverage for males and females respectively being 77.4 and 76.2 per cent. The BCG vaccination coverage was higher for children in urban areas (82.8 per cent) than among children in rural areas (74.4 per cent). The BCG vaccination coverage rate, as expected, seems to have a close link with the level of mothers' education. The BCG vaccination coverage ranged from 69.7 per cent for children of mothers with no education to 83.9 per cent for children of mothers with primary education, and to 88.5 per cent for children of mothers with secondary or higher education. The BCG vaccination coverage rate also has a close link with the economic status of the household. The BCG vaccination coverage was 61.4 per cent in the case of children belonging to households in the poorest quintile compared to 91.6 per cent for children from households in the richest quintile. The BCG vaccination coverage rate ranged from 88.8 per cent in Gezira State to 59.4 per cent in West Darfur. The vaccination coverage rate was more than 80 per cent in six States (Northern, Gedarf, Khartoum, Gezira, Sinnar and Blue Nile) and below 70 per cent in three States (Red Sea, West Darfur and South Darfur). (Table CH.2)

Polio immunisation coverage: The SHHS2 data indicated that 41.4 per cent of children age 12-23 months had received Oral Polio Vaccine (OPV) at birth, 86.2 per cent received OPV 1, 80.3 per cent received OPV 2 and 64.8 per cent received OPV 3 at any time up to the date of the survey. There was only a slight difference in polio vaccine coverage rate by gender, the polio3 vaccine coverage for males and females respectively being 63.6 per cent and 66.0 per cent. The polio3 vaccine coverage was slightly higher among children in urban areas (66.4 per cent) than among children in rural areas (64.1 per cent). The polio vaccine coverage rate was only 59.2 per cent for children of mothers with no education compared to 71.8 per cent for children of mothers with primary education, and 71.0 per cent for children of mothers with secondary or higher education. The polio vaccine coverage rate also has a close link with the economic status of the household, the coverage rate being 54.8 per cent in the case of children belonging to households in the poorest quintile compared to 73.3 per cent for children from households in the richest quintile. The Polio3 vaccination coverage rate ranged from

74.6 per cent in Gedarf State to 47.8 per cent in Red Sea State. The polio3 vaccination coverage rate was more than 70 per cent in seven States (Northern, Kassala, Gedarf, Khartoum, Gezira, White Nile, Sinnar and Blue Nile) and below 60 percent in six States (River Nile, Red Sea, Kassala, North Kordofan, South Kordofan and West Darfur). (Table CH.1)

DPT HB HIB (Pentavalent vaccine) immunisation coverage: The SHHS2 data indicated that 78.7 per cent of children age 12-23 months had received DPT HB HIB1 vaccine, 71.1 per cent received DPT HB HIB 2, and 61.3 per cent received DPT HB HIB 3 at any time up to the date of the survey. There was only a slight difference in DPT HB HIB 3 vaccination coverage rate by gender, the DPT HB HIB 3 vaccination coverage for males and females respectively being 60.8 per cent and 61.7 per cent. The DPT HB HIB 3 vaccination coverage was higher among children in urban areas (70.3 per cent) than among children in rural areas (57.6 per cent). The DPT HB HIB 3 vaccination coverage rate was only 52.3 per cent for children of mothers with no education compared to 71.5 per cent for children of mothers with primary education, and 73.7 per cent for children of mothers with secondary or higher education. The DPT HB HIB 3 vaccination coverage rate also has a close link with the economic status of the household, the coverage rate being only 41.8 per cent in the case of children belonging to households in the poorest quintile compared to 86.3 per cent for children from households in the richest quintile. The DPT HB HIB 3 vaccination coverage rate ranged from 79.3 per cent in Gezira State to 36.0 per cent in South Darfur State. The DPT HB HIB 3 vaccination coverage rate was more than 70 per cent in six States (Northern, Khartoum, Gezira, White Nile, Sinnar and Blue Nile) and below 50 percent in four States (North Kordofan, North Darfur, West Darfur and South Darfur).

Measles immunisation coverage: The SHHS2 data indicated that 70.1 per cent of children age 12-23 months had received measles vaccination at any time up to the date of the survey. There was no difference in measles vaccination coverage rate by gender, the BCG vaccination coverage for males and females respectively being 70.2 and 70.1 per cent. The measles vaccination coverage was higher for children in urban areas (75.9 per cent) than among children in rural areas (67.8 per cent).

The measles vaccination coverage rate ranged from 60.5 per cent for children of mothers with no education to 79.5 per cent for children of mothers with primary education, and to 86.8 per cent for children of mothers with secondary or higher education. The measles vaccination coverage was only 52.7 per cent in the case of children belonging to households in the poorest quintile compared to 92.2 per cent for children from households in the richest quintile. The Measles vaccination coverage rate ranged from 85.7 per cent in Gezira State to 56.1 per cent in North Kordofan State. The Measles vaccination coverage rate was more than 80 per cent in three States (Northern, Gedarf, and Gezira) and below 60 per cent in four States (Red Sea, North Kordofan, West Darfur and South Darfur). (Table CH.2)

Fully immunised children: The SHHS2 data indicated that only half (49.4 per cent) of Sudan's children age 12-23 months were fully immunised with BCG vaccine against tuberculosis, three doses of polio vaccine against polio, three doses of Pentavalent against DPT (diphtheria, pertussis and tetanus), Hepatitis B (HB), and Haemophilus influenzae (HIB) and measles vaccine before their first birthday. This leaves the rest of the children age 12-23 months unprotected against life-threatening diseases. The percentage of fully immunised children was slightly higher among females (50.3 per cent) than that among male children (48.5 per cent). The percentage of fully immunised children was higher for children in urban areas (56.2 per cent) than among children in rural areas (46.6 per cent). The percentage of fully immunised children ranged from 41.3 per cent for children of mothers with no education to 58.4 per cent for children of mothers with primary education, and to 60.8 per cent for children of mothers with secondary or higher education. The percentage of fully immunised children was only 35.3 per cent in the case of children belonging to households in the poorest quintile compared to 67.9 per cent for children from households in the richest quintile. The percentage of fully immunised children at any time up to the date of the survey ranged from 65.1 per cent in Sinnar State to 34.1 per cent in South Darfur State. The percentage of fully immunised children was more than 60 per cent in five States (Northern, Khartoum, Gezira, Sinnar, and Blue Nile) and below 40 per cent in four States (Red Sea, North Kordofan, West Darfur and South Darfur). (Table CH.2)

The SHHS2 data indicates that the percentage of women aged 15-49 years with a live birth in the last two years protected against neonatal tetanus was only 54.7. The percentage of women who received at least two doses of tetanus toxoid (TT) vaccine during last pregnancy was only 34.1 per cent.

The percentage of women aged 15-49 years with a live birth in the last two years protected against neonatal tetanus was higher among women in urban areas (62.2 per cent) than those in rural areas (51.9 per cent). However, there was only a marginal difference in the percentage of women who received at least two doses of tetanus toxoid (TT) vaccine during last pregnancy between those living in urban areas (34.9 per cent) and those living in rural areas (33.7 per cent).

The level of education of the woman is related to the likelihood of neonatal tetanus protection. For instance, the percentage of women aged 15-49 years who were protected against neonatal tetanus was only 41.8 per cent for women with no education, compared to 64.3 per cent for women with primary education and 71.8 per cent for women with secondary and higher levels of education. Similarly, the percentage of women aged 15-49 years who received at least two doses of tetanus toxoid (TT) vaccine during last pregnancy was only 28.5 per cent for women with no education, compared to 38.7 per cent for women with primary education and 41.4 per cent for women with secondary and higher levels of education.

The economic status of the women also plays a key role; the percentage of women age 15-49 years with a live birth in the last two years protected against neonatal tetanus was 70.0 for those from households in the richest quintile compared to 41.1 for those belonging to households in the poorest quintile. Similarly, the percentage of women aged 15-49 years who received at least two doses of tetanus toxoid (TT) vaccine during last pregnancy was 38.4 for those from households in the richest quintile compared to 28.7 for those belonging to households in the poorest quintile.

The percentage of women aged 15-49 years who have had a live birth within the last 2 years protected against neonatal tetanus varied significantly by State. The proportion of women protected against neonatal tetanus ranged from 67.5 per cent in Gezira State to 41.5 per cent in Blue Nile State.

The percentage of women aged 15-49 years who received at least two doses of tetanus toxoid (TT) vaccine during last pregnancy also varied by State. The percentage of women aged 15-49 years who received at least two doses of tetanus toxoid (TT) vaccine during last pregnancy was highest in North Kordofan State (36.9 per cent) and the lowest in Red Sea State (25.4 per cent).

Care of Illness

Management/treatment of diarrhoea

Diarrhoea is the second leading cause of death among children under five worldwide. Most diarrhoea-related deaths in children are due to dehydration from loss of large quantities of water and electrolytes from the body in liquid stools. Management of diarrhoea – either through oral rehydration salts (ORS) or a recommended home fluid (RHF) - can prevent many of these deaths. Preventing dehydration and malnutrition by increasing fluid intake and continuing to feed the child are also important strategies for managing diarrhoea.

A key goal is to reduce by one half deaths due to diarrhoea among children under five by 2010 compared to 2000 (A World Fit for Children). In addition, the World Fit for Children calls for a reduction in the incidence of diarrhoea by 25 per cent.

In the SHHS2 questionnaire, mothers (or caretakers) were asked to report whether their child had had diarrhoea in the two weeks prior to the survey. If so, the mother was asked a series of questions about what was given to the child to drink and eat during the episode of diarrhoea and whether this was more or less than the child usually drank and ate.

Incidence of diarrhoea: The SHHS2 data indicated that overall, 26.8 per cent of under-five children had diarrhoea in the two weeks preceding the survey (Table CH.4). The peak of diarrhoea prevalence (36.3 per cent) was observed among children aged 12-23 months. There was slight difference in the proportion of under-five children who had diarrhoea in the two weeks preceding the survey in rural and urban areas. The diarrhoea prevalence rate was lower among children in urban areas (22.7 per cent) than that among children in rural areas (28.3 per cent). The level of education of the mothers appears to be related to the likelihood of diarrhoea among children aged 0-59 months. For instance, the percentage of children aged 0-59 years with diarrhoea in the last two weeks was 27.6 per cent among children of mothers with no education compared to 21.9 per cent for children of mothers with secondary and higher levels of education. Diarrhoea prevalence was reported from all regions, the percentage of children aged 0-59 months who had diarrhoea ranged from 33.9 per cent in South Darfur State to 17.5 per cent in River Nile State.

Management/treatment of diarrhoea with oral rehydration solutions and recommended homemade fluids

Table CH.4 also shows the percentage of children age 0-59 months with diarrhea who received treatment with oral rehydration solutions and recommended homemade fluids during the episode of diarrhoea. Since mothers were able to name more than one type of liquid, the percentages do not necessarily add to 100.

	Had diarrhoea in last two weeks	Number of children age 0-59 months	Children with diarrhoea who received:		ORS or any recommended homemade fluid	Number of children aged 0-59 months with diarrhoea
			ORS (Fluid from ORS packet, ORADEX)	Any recommended homemade fluid		
Sex						
Male	26.8	6742	22.1	26.9	40.7	1806

SUDAN (TOTAL)	26.8	13282	22.0	25.8	40.0	3555

Treatment of diarrhoea with oral rehydration salt (ORS): About 22.0 per cent of children age 0-59 months with diarrhoea (in the last two weeks preceding the survey) received ORS (i.e. fluid from ORS packet, ORADEX). Very little difference was noticed between boys (40.7 per cent) and girls (39.4 per cent) in terms of those who received ORS. The percentage of under-five children with diarrhoea and received ORS increases from 18.7 per cent in the case of children aged below 12 months to 24.9 per

cent for children aged 12-23 months and then decreases to 24.5 per cent for children aged 24-35 months, to 20.2 per cent for children aged 36-47 months and to 20.5 per cent for children aged 48-59 months. The percentage of children who had diarrhoea in the two weeks preceding the survey and received ORS was slightly higher among those in urban areas (23.2 per cent) than that for children in rural areas (21.6 per cent). The education level of the mother did not have any influence on children with diarrhoea who received ORS. However, the percentage of children who received fluid from ORS packet was found to be higher among children from households in the second wealth index quintile (25.3 per cent) than those from households in the poorest quintile (21.1 per cent) and those from households in the richest quintile (15.7 per cent).

Treatment of diarrhoea with any recommended homemade fluid (home management of diarrhoea): The SHHS data shows that about 25.8 per cent of children age 0-59 months with diarrhoea (in the last two weeks preceding the survey) received recommended homemade fluids. The percentage of children who received recommended homemade fluid increases from 20.0 in the case of children aged below 12 months to 28.4 for children aged 12-23 months, and then decreases to 25.0 for children aged 48-59 months. The percentage of children who had diarrhoea in the two weeks preceding the survey and received any recommended homemade fluid was higher among those in urban areas (30.0 per cent) than that for children in rural areas (24.5 per cent). The level of education of the mothers appears to be related to the likelihood of treatment for children aged 0-59 months with diarrhoea. For instance, the percentage of children aged 0-59 years with diarrhoea who received any recommended homemade fluid was 23.4 per cent for children of mothers with no education, compared to 29.1 per cent for children of women with primary education and 29.7 per cent for children of women with secondary and higher levels of education. The percentage of children who received homemade fluid was higher among children belonging to households in the richest quintile (33.7 per cent) than that among children from households in the poorest quintile (22.8 per cent).

Treatment of diarrhoea with ORS or any recommended homemade fluid: Approximately 40.0 per cent of children with diarrhoea received one or more of the recommended home treatments (i.e., they were treated with ORS or any recommended homemade fluid), while 60 per cent received no treatment. Very little difference was noticed between boys (40.7 per cent) and girls (39.4 per cent) in terms of those who received ORS or any recommended homemade fluid. The percentage of under-five children who had diarrhoea in the two weeks preceding the survey and received ORS or any recommended homemade fluid was higher among those in urban areas (46.3 per cent) than that for children in rural areas (38.1 per cent). The percentage of children with diarrhoea who received ORS or any recommended homemade fluid increases from 34.4 per cent for children aged below 12 months to 43.4 per cent for children aged 12-23 months, to 43.9 per cent for children aged 24-35 months, and then declines to 40.1 per cent for children aged 36-47 months and to 38.2 per cent for children aged 48-59 months. The percentage of under-five children who had diarrhoea in the two weeks preceding the survey and received ORS or any recommended homemade fluid was higher among those in urban areas (46.3 per cent) than that for children in rural areas (38.1 per cent). The level of education of the mothers appears to be related to the likelihood of treatment for children aged 0-59 months with diarrhoea. For instance, the percentage of children aged 0-59 years with diarrhoea who received ORS or any recommended homemade fluid was 38.0 per cent for children of mothers with no education, compared to 42.8 per cent for children of women with primary education and 44.2 per cent for children of women with secondary and higher levels of education. The percentage of children aged 0-59 years with diarrhoea in the last two weeks who received ORS or any recommended homemade fluid was higher among children from households in the richest quintile (43.8) than that for those belonging to households in the poorest quintile (36.3). The percentage of under-five children who had diarrhoea in the two weeks preceding the survey and received ORS or any recommended homemade fluid ranged from 54.8 per cent in Northern State to 33.9 per cent in North Darfur State.

Feeding practices during diarrhoea

Table CH.5 presents the feeding practices during diarrhea, i.e. percent distribution of children aged 0-59 months with diarrhoea in the last two weeks by amount of liquids and food given during episode of diarrhea. The SHHS2 data related to drinking practices of children during diarrhoea indicates that about 42.2 per cent of children with diarrhoea were given less than usual to drink, 30.7 per cent of them were given about the same to drink and 21.9 per cent of them were given more than usual to drink while 4.5 per cent of children were given nothing to drink during the episode of diarrhoea. Very little difference was noted between boys (41.5 per cent) and girls (42.9 per cent) in terms of those who were given less liquid than usual to drink while there was some difference between boys (32.4 per cent) and girls (29.0 per cent) who were given about the same amount to drink. There was also a slight difference between boys (20.8 per cent) and girls (23.0 per cent) who were given more than usual amount of liquid to drink. Very little difference was noticed between boys (4.7 per cent) and girls (4.4 per cent) who were given nothing to drink.

The percentage of children who were given less than usual to drink during the episode of diarrhoea increases from 36.5 in the case of children aged below 12 months to 46.1 among children aged 12-23 months and then decreases to 40.7 for children aged 24-35 months, then increases to 40.7 among aged 36-47 months and to 47.1 among children aged 48-59 months. The percentage of children who were given about the same to drink during the episode of diarrhoea decreases from 32.6 in the case of children aged below 12 months to 28.3 for children aged 12-23 months and then increases to 31.8 for children aged 24-35 months, then increases to 30.9 for children aged 36-47 months and to 29.3 per cent for children aged 48-59 months. The percentage of children who were given more than usual to drink during the episode of diarrhoea increases from 16.6 in the case of children aged below 12 months to 23.4 for children aged 12-23 months and to 26.4 for children aged 24-35 months, then decreases to 22.4 for children aged 36-47 months and to 21.9 for children aged 48-59 months.

There is little influence of educational levels of mothers on the drinking practices during diarrhoea among children aged 0-59 months. However, there is some impact of economic levels of mothers on the drinking practices of children during diarrhoea. The proportion of children who were given less than usual amount of liquids to drink declined from 43.6 per cent for children of mothers from households in the poorest quintile to 39.2 per cent for children of mothers from households in the richest quintile. The proportion of children who were given about the same amount of liquids increased from 27.4 per cent for children of mothers from households in the poorest quintile to 31.4 per cent for children of mothers from households in the richest quintile. The proportion of children who were given more than the usual to drink decreased from 25.3 per cent for children of mothers from households in the poorest quintile to 22.8 per cent for children of mothers from households in the richest quintile.

The SHHS2 data related to eating practices during diarrhoea indicates that about 59.1 per cent of children with diarrhoea were given less than usual to eat, while 25.3 per cent of them were given about the same to eat and 1.8 per cent of them were given more than usual to eat and 4.0 per cent of children with diarrhoea were given nothing to eat during the episode of diarrhoea. The percentage of children who were given less than usual/required amount of food to eat during episode of diarrhoea increases from 40.3 in the case of children aged below 12 months to 66.6 among children aged 12-23 months and then decreases to 65.9 for children aged 24-35 months, and to 65.2 among aged 36-47 months and then increases to 67.1 among children aged 48-59 months. The percentage of children who were given about the same amount of required food to eat during episode of diarrhoea increases from 19.1 in the case of children aged below 12 months to 30.6 for children in the age group 36-47 months and then decreases to 28.1 for children age 48-59 months. There is little influence of educational levels of mothers on the eating practices of children during diarrhoea. However, there is some impact of economic levels of mothers on the eating practices of children during diarrhoea. The proportion of children who were given less than usual to eat during the episode of diarrhoea declined from 63.4 per cent for children of mothers from households in the poorest quintile to 53.7 per cent for children of mothers from households in the richest quintile. The proportion of children who were given about the same to eat during the episode of diarrhoea increased from 21.3 per cent for children of mothers from households in the poorest quintile to 32.7 per cent for children of mothers from households in the richest quintile.

There are differences among states in terms of feeding practices (both drinking and eating practices) during diarrhoea. The proportion of children (age 0-59 months) who were given less than usual to drink during the episode of diarrhoea ranged from 55.9 per cent in Northern State to 29.9 per cent in Blue Nile State. The proportion of children who were given about the same to drink during episode of diarrhoea ranged from 42.5 per cent in Blue Nile State to 20.7 per cent in South Darfur State. The proportion of children who were given more than usual to drink during episode of diarrhoea ranged from 9.3 per cent in Kassala to 31.8 per cent in South Darfur.

There are also differences among states in terms of eating practices during diarrhoea. The proportion of children (age 0-59 months) who were given less than usual to eat during episode of diarrhoea ranged from 69.6 per cent in South Darfur State to 50.4 per cent in Blue Nile State. The proportion of children who were given about the same to eat during episode of diarrhoea ranged from 13.5 per cent in South Kordofan State to 37.5 per cent in Gezira State. The proportion of children who were given more than usual to eat during episode of diarrhoea ranged from 4.5 per cent in North Darfur to 0.1 per cent in Khartoum.

Oral rehydration therapy with continued feeding and other treatments

Table CH.6 presents information on oral rehydration therapy with continued feeding and other treatments for children with diarrhoea. It indicates the percentage of children age 0-59 months with diarrhoea in the last two weeks preceding the survey who received ORS or increased fluid, oral rehydration therapy (ORT), and oral rehydration therapy with continued feeding, percentage of children with diarrhoea who received other treatments, and percentage of children who were not given any treatment or drug. Very little difference was noticed between boys and girls with diarrhoea who received oral rehydration therapy with continued feeding and other treatments. However, there was noticeable difference between children of different age groups who received oral rehydration therapy with continued feeding and other treatments. The education level of the mothers was found to impact the proportion of children age 0-59 months with diarrhoea who received oral rehydration therapy with continued feeding. The economic status of the household was found to have some impact on the proportion of children (age 0-59 months) with diarrhoea who received oral rehydration therapy with continued feeding and other treatments. The education level of the mothers was found to impact the proportion of children age 0-59 months with diarrhoea who received oral rehydration therapy with continued feeding. The economic status of the household was found to have some impact on the proportion of children (age 0-59 months) with diarrhoea who received oral rehydration therapy with continued feeding and other treatments. About a quarter of children (24.9 per cent) were not given any treatment or drug during the episode of diarrhoea.

Children with diarrhoea who received ORS or increased fluid: The SHHS2 data indicated that overall 38.6 per cent of children with diarrhoea received ORS or increased fluids during the episode of diarrhoea. Very little difference was noticed between boys and girls with diarrhoea who received ORS or increased fluids. About 37.9 per cent of boys with diarrhoea received ORS or increased fluid compared to 39.4 per cent of girls. Very little difference was also noticed between children with diarrhoea in rural and urban areas who received ORS or increased fluids. About 38.1 per cent of children in urban areas received ORS or increased fluid compared to 38.8 per cent of children in rural areas. The proportion of children with diarrhoea who received ORS or increased fluids increased from 31.8 per cent among children aged 0-11 months to 41.9 per cent among those aged 12-23 months, and to 44.4 per cent among children aged 24-35 months, and then declined to 38.0 among those aged 36-47 months and to 37.5 per cent among those aged 48-59 months. The proportion of children with diarrhoea who received ORS or increased fluids was higher among children of mothers with no education (39.4 per cent) than that for children of mothers with secondary or higher level of education (36.4 per cent). The proportion of children with diarrhoea who received ORS or increased fluids showed a declining trend from 41.3 per cent among children from households in the poorest quintile to 35.3 per cent among children from households in the richest quintile. The proportion of children with diarrhoea who received who received ORS or increased fluids during the episode of diarrhoea ranged from 28.2 per cent in Northern State to 48.5 per cent in Blue Nile State.

Children with diarrhoea who received ORT: The SHHS2 data indicates that overall 52 per cent received ORT (ORS or recommended homemade fluids or increased fluids) during the episode of diarrhoea. Very little difference was noticed between boys and girls with diarrhoea who received oral

Table 6.6: Oral rehydration therapy with continued feeding and other treatments

[1] SHHS indicator 3.8

rehydration therapy. About 52.1 per cent of boys received ORT compared to 51.8 per cent of girls. Very little difference was also noticed between children with diarrhoea in rural and urban areas who received ORT during the episode of diarrhoea. About 54.3 per cent of children in urban areas received ORT compared to 51.3 per cent of children in rural areas. The proportion of children with diarrhoea who received ORT increased from 44.7 per cent among children aged 0-11 months to 55.6 per cent among those aged 12-23 months, and to 57.5 per cent among children aged 24-35 months, and then declined to 51.6 per cent among those aged 36-47 months and to 50.6 per cent among those aged 48-59 months. The proportion of children with diarrhoea who received ORT was lower among children of mothers with no education (50.1 per cent) than that for children of mothers with secondary or higher level of education (54.4 per cent). There was no difference in the proportion of children with diarrhoea who received ORT among those from households in the poorest quintile (52.4 per cent) and those from households in the richest quintile (52.1 per cent). The proportion of children with diarrhoea who received ORT ranged from 41.0 per cent in Kassala State to 60.9 per cent in South darfur State.

Children with diarrhoea who received ORT with continued feeding: The SHHS2 data indicated that overall 11.8 per cent received ORT with continued feeding. The proportion of children with diarrhoea who received ORT with continued feeding ranged from 7.4 per cent in South Darfur State to 19.4 per cent in Blue Nile State (Figure 6.8).

Very little difference was noticed between boys and girls with diarrhoea who received ORT with continued feeding. About 12.4 per cent of boys received ORT with continued feeding compared to 11.2 per cent of girls. Very little difference was also noticed between children with diarrhoea in rural and urban areas who received oral rehydration therapy with continued feeding. About 12.6 per cent of children in urban areas received ORT with continued feeding compared to 11.6 per cent of children in rural areas. The proportion of children with diarrhoea who received ORT with continued feeding

increased from 8.1 per cent among children aged 0-11 months to 12.7 per cent among those aged 12-23 months, to 13.9 per cent among children aged 24-35 months, and to 14.5 per cent among those aged 36-47 months and then declined to 11.1 per cent among those aged 48-59 months. The proportion of children with diarrhoea who received ORT with continued feeding was slightly lower among children of mothers with no education (11.5 per cent) than that for children of mothers with secondary or higher level of education (13.2 per cent). The proportion of children with diarrhoea who received ORT with continued feeding showed an increasing trend from 10.9 per cent among children from households in the poorest quintile to 16.8 per cent among children from households in the richest quintile. The proportion of children with diarrhoea who received ORT with continued feeding ranged from 7.4 per cent in South Darfur State to 19.4 per cent in Blue Nile State (Figure 6.8).

Children with diarrhoea who received other treatment: The SHHS2 data indicated that overall 58.8 per cent of children with diarrhoea received other treatment, the most common treatment being the use of antibiotic (pill or syrup). About 40.8 per cent of children with diarrhoea received antibiotic (pill or syrup). There was hardly any difference between boys and girls with diarrhoea who received antibiotic (pill or syrup). About 41.0 per cent of boys received antibiotic treatment compared to 40.7 per cent of girls. Very little difference was also noticed between children with diarrhoea in rural and urban areas who received antibiotic (pill or syrup). About 39.9 per cent of children in urban areas received antibiotic (pill or syrup) compared to 41.1 per cent of children in rural areas. The proportion of children with diarrhoea who received antibiotic (pill or syrup) increased from 36.9 per cent among children aged 0-11 months to 42.4 per cent among those aged 12-23 months, then declined to 41.5 per cent among children aged 24-35 months, and then increased to 41.9 per cent among those aged 36-47 months and to 44.4 per cent among those aged 48-59 months. The proportion of children with diarrhoea who received antibiotic (pill or syrup) was slightly lower among children of mothers with no education (41.1 per cent) than that for children of mothers with secondary or higher level of education (43.9 per cent). The proportion of children with diarrhoea who received antibiotic (pill or syrup) declined from 40.0 per cent among children from households in the poorest quintile to 43.9 per cent among children from households in the richest quintile. The proportion of children with diarrhoea who received antibiotic (pill or syrup) ranged from 24.1 per cent in White Nile State to 55.9 per cent in Gadarif State.

Care Seeking and Antibiotic Treatment of Pneumonia

Pneumonia is the leading cause of death in children and the use of antibiotics for treatment of Under-five children with suspected pneumonia is a key intervention. Children with suspected pneumonia are those who had an illness with a cough, accompanied by rapid or difficult breathing and whose symptoms were NOT due to a problem in the chest and a blocked nose. A World Fit for Children goal is to reduce by one-third the deaths due to acute respiratory infections.

Table CH.7 presents the prevalence of suspected pneumonia among children age 0-59 months and, if care was sought outside the home, the site of care. It also provides information relating to the percentage of children age 0-59 months with suspected pneumonia in the last two weeks preceding the survey who were taken to a health provider and percentage of children who were given antibiotics.

Prevalence of suspected pneumonia: The SHHS2 data indicates that about 18.7 per cent of children aged 0-59 months were reported to have had symptoms of pneumonia during the two weeks preceding the survey. Very little difference between boys (18.9 per cent) and girls (18.5 per cent) was observed with regard to suspected pneumonia. There was slight difference with regard to suspected pneumonia between children from urban areas (17.6 per cent) and children from rural areas (19.1 per cent). There was slight difference with regard to suspected pneumonia between children of mothers with no education (18.7 per cent), children of mothers with primary education (19.8 per cent) and children of mothers with secondary or higher levels of education (16.3 per cent). There was also some difference with regard to suspected pneumonia between children from households in the poorest quintile (24.7 per cent) and children from households in the richest quintile (17.2 per cent).

Table 6.7 (continued): Care seeking for suspected pneumonia and antibiotic use during suspected pneumonia (Percentage of children age 0-59 months with suspected pneumonia in the last two weeks who were taken to a health provider and percentage of children who were given antibiotics, Sudan, 2010)

with suspected pneumonia taken to private facilities such as private hospital/clinic, private physician, pharmacy, mobile clinic and other private medical facilities was 13.3 per cent. Very little difference between boys (56.6 per cent) and girls (54.9 per cent) was observed with regard to children with suspected pneumonia taken to an appropriate health provider. The proportion of children age 0-59 years with suspected pneumonia who were taken to an appropriate health provider was higher among children from urban areas (66.8 per cent) than for children from rural areas (51.9 per cent). There was also noticeable difference (with regard to those who were taken to an appropriate health provider) between children of mothers/caretakers with no education (50.8 per cent), children of mothers/caretakers with primary education (58.7 per cent) and children of mothers/caretakers with secondary or higher levels of education (72.7 per cent) who were taken to an appropriate health provider. There was also significant difference (with regard to those who were taken to an appropriate health provider) between children from households in the poorest quintile (40.1 per cent) and children from the households in the richest quintile (71.2 per cent). The proportion of children with suspected pneumonia and who were taken to an appropriate health provider increased from 54.3 per cent among children aged 0-11 months to 59.4 per cent among those aged 12-23 months, and then declined to 58.5 per cent among children aged 24-35 months to 53.0 per cent among those aged 36-47 months and to 52.0 per cent among those aged 48-59 months. The proportion of children aged 0-59 months reported to have had symptoms of pneumonia during the two weeks preceding the survey and taken to an appropriate provider ranged from 79.6 per cent in Red Sea State to 31.8 per cent in South Darfur State.

Antibiotic treatment for suspected pneumonia: Table CH.7 presents the use of antibiotics for the treatment of suspected pneumonia in under-five children by sex, age, region, residence, age, and socioeconomic factors. In Sudan, 66.1 per cent of under-five children with suspected pneumonia during the last two weeks preceding the survey had received an antibiotic. Very little difference between boys (65.7 per cent) and girls (66.5 per cent) was observed with regard to children who had received antibiotics. The percentage of under-five children with suspected pneumonia who had received an antibiotic in the last two weeks preceding the survey was considerably higher in urban

areas (72.5 per cent) than that for children in rural areas (63.9 per cent). The proportion of children with suspected pneumonia and who received an antibiotic increased from 61.3 per cent among children aged 0-11 months to 70.0 per cent among those aged 12-23 months, and then declined to 67.5 per cent among children aged 24-35 months and to 66.0 per cent among those aged 36-47 months and then marginally increased to 66.1 per cent among those aged 48-59 months. There was also significant difference (with regard to those who received antibiotics) between children of mothers/caretakers with no education (61.2 per cent), children of mothers/caretakers with primary education (69.8 per cent) and children of mothers/caretakers with secondary or higher levels of education (78.8 per cent). The proportion of under-five children with suspected pneumonia during the last two weeks preceding the survey who had received an antibiotic was higher for children belonging to households in the poorest quintile (55.2 per cent) than that for children from households in the richest quintile (76.2 per cent). The proportion of children aged 0-59 months reported to have had symptoms of pneumonia during the two weeks preceding the survey and had received antibiotics ranged from 50.8 per cent in South Darfur State to 80.9 per cent in Kassala State.

The symptoms that would cause mothers/caretakers to take a child immediately to a health facility

Table 6.8 indicates the percentage of mothers and caretakers of children age 0-59 months by symptoms that would cause them to take the child immediately to a health facility, and percentage of mothers who recognise fast and difficult breathing as signs for seeking care immediately.

The mothers/caretakers interview during SHHS2 indicated several symptoms that would lead them to take a child to a health facility. About 73.7 per cent of the mothers indicated that they would take a child immediately to a health facility if the child was not able to drink or breast feed. About 43.5 per cent of mothers/caretakers identified becoming sicker as the symptom for taking children immediately to a health care provider. The percentages of mothers/caretakers who thought that a child should be taken to a health facility if the child showed the following symptoms were as follows: develops a fever (73.7 per cent); has fast breathing (14.0 per cent); has difficulty breathing (19.6 per cent); has blood in stool (7.1 per cent); is drinking poorly (3.6 per cent).

Knowledge of the two danger signs of pneumonia

Mothers' knowledge of the danger signs of pneumonia is an important determinant of care-seeking behaviour. Overall, only 4.5 per cent of women knew of the two danger signs of pneumonia – fast and difficult breathing. The percentage of mothers/caretakers who recognise the two danger signs of pneumonia was higher among mothers in urban areas (9.5 per cent) than among mothers in rural areas (2.5 per cent). The percentage of mothers/caretakers who recognised the two danger signs of pneumonia was higher among mothers with secondary or higher education (8.6 per cent) than among mothers with primary education (6.2 per cent) and mothers with no education (2.0 per cent). Similarly, the percentage of mothers/caretakers who recognised the two danger signs of pneumonia was higher among mothers from the households in the richest quintile (10.8 per cent) than those belonging to the poor households in the poorest quintile (1.3 per cent). The percentage of mothers/caretakers who recognised the two danger signs of pneumonia was highest in Khartoum (14.7 per cent) and the lowest in South Kordofan (0.2 per cent).

Solid Fuel Use

More than three billion people around the world rely on solid fuels (biomass and coal) for their basic energy needs, including cooking and heating. Cooking and heating with solid fuels leads to high levels of indoor smoke, a complex mix of health-damaging pollutants. The main problem with the use of solid fuels is products of incomplete combustion, including carbon monoxide (CO), polyaromatic hydrocarbons, sulphur dioxide (SO₂) and other toxic elements. Use of solid fuels increases the risks of acute respiratory illness, pneumonia, chronic obstructive lung disease, cancer, and possibly tuberculosis, low birth weight, cataracts, and asthma.

The primary indicator used in SHHS is Solid fuel use, i.e. the proportion of household members in households that use solid fuels as the primary source of domestic energy to cook. Table 6.9 shows the percent distribution of household members according to type of cooking fuel used by the household, and percentage of household members living in households using solid fuels for cooking. Overall, approximately two-thirds (63.2 per cent) of all households in Sudan were found to be using solid fuels for cooking. The table also clearly shows that the overall percentage was high due to high level of use of wood (42.7 per cent) for cooking purposes, followed by use of charcoal (18.9 per cent). In all about 36.5 per cent of the households were found to use gas for cooking purposes (Use of solid fuels is significantly lower in urban areas (43.3 per cent) than in rural areas where almost three-fourths of the households (72.4 per cent) are using solid fuels. Differentials with respect to educational level of the household head are also significant. The proportion of household members living in households using solid fuels for cooking was 74.8 per cent among households with household head with no education compared to 37.0 per cent among households with household heads with secondary or higher level of education. Differentials with respect to household wealth are also significant. The findings show that use of solid fuels is very uncommon among the households in the richest quintile (7.4 per cent) while it is very common among households in the poorest quintile (100.0 per cent)

The SHHS2 data shows that the use of solid fuels is very uncommon among households in Khartoum (15.1 per cent) (since most of the households in Khartoum have access to cooking gas) while it was very common in Blue Nile State (96.1 per cent), South Kordofan State (97.9 per cent), North Darfur State (98.3 per cent), West Darfur State (99.3 per cent) and South Darfur State (98.4 per cent) (Figure 6.11)

Solid fuel use by place of cooking

Solid fuel use alone is a poor proxy for indoor air pollution, since the concentration of the pollutants is different when the same fuel is burnt in different stoves or fires. Use of closed stoves with chimneys minimizes indoor pollution, while open stove or fire with no chimney or hood means that there is no protection from the harmful effects of solid fuels. Solid fuel use by place of cooking is depicted in Table 6.10.

Table 6.10 presents the percent distribution of household members in households using solid fuels by place of cooking. Overall, approximately less than one-half (47.0 per cent) of all households in North Sudan were found to be cooking in a separate room used as a kitchen while 19.3 per cent of household members were cooking elsewhere in the house, 22.0 per cent in a separate building and 9.4 per cent outdoors.

	Place of cooking:							Number of household members in households using solid fuels for cooking
	In a separate room used as kitchen	Elsewhere in the house	In a separate	Outdoors	Other	Missing	Total

Cooking in a separate room used as kitchen was found to be significantly higher in urban areas (50.8 percent) than in rural areas (46.0 percent). Differentials with respect to educational level of the household head are also significant. The proportion of household members cooking in a separate room used as kitchen was higher (50.8 per cent) among households with household head with no education compared to 49.6 per cent among households with household head with primary education and 53.4 per cent among households with household head with secondary or higher education levels.

Differentials with respect to household wealth are also significant. The findings show that the proportion of household members cooking in a separate room used as kitchen was more common among the households in the richest quintile (57.0 per cent) compared to households (33.6 per cent) in the poorest quintile.

The SHHS2 findings show that cooking in a separate room used as kitchen was more common among households in Northern State (98.2 per cent), North Darfur (89.1 per cent), West Darfur (77.5 per cent), South Kordofan (68.6 per cent) and Khartoum State (66.6 per cent), while it was very uncommon in Blue Nile State (4.5 per cent) and South Darfur (0.5 per cent).

Malaria Prevention and Control

Malaria is a leading cause of death of children under age five in Sudan. It also contributes to anaemia in children and is a common cause of school absenteeism. Preventive measures, especially the use of mosquito nets treated with insecticide (ITNs), can dramatically reduce malaria mortality rates among children. In areas where malaria is common, international recommendations suggest treating any fever in children as if it were malaria and immediately giving the child a full course of recommended anti-malarial tablets. Children with severe malaria symptoms, such as fever or convulsions, should be taken to a health facility. Also, children recovering from malaria should be given extra liquids and food and, for younger children, should continue breastfeeding. In Sudan the program strategy is to increase coverage and use of the most effective, available, and evidence-based interventions that meet international standards to achieve high impact. The key strategic interventions for this concept note are:

- Artemisinin-based combination treatment (ACT) rollout in all health facilities, and through home-based malaria management in unreachable communities
- Improve malaria diagnosis through training and using microscopy and RDTs at Health facilities
- Distribution of bed nets (LLINs) for disease prevention through mass campaigns and routine distribution

Significant investments have been made over the past five years in malaria control including the distribution of over 6 million long lasting insecticide treated nets, the supply of artemisinin combination therapies to over 90% of government health facilities; the scaling up of insecticidal spraying in several areas; and the training of large number of health workers in appropriate malaria case management

LLINs distribution is focused mainly in Darfur states, Kordofan states, Blue Nile, White Nile, Gadaref and Kassala states based on the prevalence of the vector and the disease

Questions on the prevalence (proportion of children 0-59 months of age who were ill with fever in the last two weeks) and treatment of fever were asked for all children under age five. The questionnaire for SHHS2 incorporated questions relating to anti-malarial treatment. Mothers were asked to report all of the medicines given to a child to treat the fever, including both medicines given at home and medicines given or prescribed at a health facility.

What about ITN usage?

Antimalarial treatment (Children under age five)

The SHHS data indicated that slightly less than one in ten (8.4 per cent) of under five children were ill with fever in the two weeks prior to the survey. The SHHS data indicated that fever prevalence peaked at 12-23 months of age. It increased from 7.6 per cent among children aged 0-11 months to 9.6 per cent among children aged 12-23 months and then declined with increasing age to 9.3 per cent among children aged 24-35 months, to 7.8 per cent among children aged 36-47 months, and to 7.7 per cent among children aged 48-59 months. Fever prevalence was found to be higher in rural areas (9.2 per cent) than in urban areas (6.3 per cent). No difference in fever prevalence was observed between boys and girls.

Fever prevalence was found to be less among children whose mothers had secondary or higher education (6.5 per cent) than among children whose mothers had primary education (8.5 per cent) and among children whose mothers had no education (8.8 per cent). Fever is also more common among children belonging to the poorest households (9.2 per cent) than among those belonging to the richest households (6.0 per cent). State differences in fever prevalence were not large, ranging from 14.2 per cent in North Kordofan to 3.2 per cent in Khartoum.

The SHHS2 data indicated that overall, 65.0 per cent of children with fever in the last two weeks were treated with an "appropriate" anti-malarial drug. However, only 43.0 per cent received anti-malarial drugs on the same or next day (within 24 hours of onset of symptoms). "Appropriate" anti-malarial drugs include chloroquine, SP (sulfadoxine-pyrimethamine), artemisine combination drugs, etc. In Sudan, 29.5 percent of children with fever were given chloroquine (3.8 per cent of children with fever were given chloroquine tablet, 4.6 per cent were given Chloroquine injection and 21.1 per cent were given chloroquine syrup) while 12.7 per cent were given SP/Fansidar tablet. Only 21.4 per cent received artemisinin combination therapy. A large percentage of children (25.9 per cent) were given other types of medicines that are not anti-malarials, including anti-pyretics such as paracetamol, panadol, acetaminophen, aspirin, or ibuprofen.

among households which had a household head with no education compared to 9.7 per cent in the case of households which had a household head with secondary or higher level of education. The proportion of adult man collecting drinking water for the household was lower at 23.1 per cent among households which had a household head with no education compared to 34.6 per cent in the case of households which had a household head with secondary or higher level of education.

As shown in Table 7.6, overall 27.1 per cent of the users of improved sanitation facilities did not share sanitation facility with others. There was not much difference in the users of a shared sanitation facility between household population using an improved sanitation facility (7.3 per cent) and household population using an unimproved sanitation facility (7.9 per cent). The percentage of users of a shared improved sanitation facility was higher among household population in urban areas (12.4 per cent) than that for users of a shared improved sanitation facility in rural areas (5.0 per cent). There was a significant difference between rural and urban areas in the proportion of users of improved sanitation facilities who used a facility not shared by other households. The proportion of users of improved sanitation facilities who used a facility not shared by other households was 46.9 per cent in urban areas compared to 17.9 per cent in rural areas. There was also a significant difference between household population in the richest and poorest quintiles who used an improved sanitation facility not shared by other households. The proportion of users of improved sanitation facilities not shared by other households was 69.8 per cent among those from households in the richest quintile compared to only 2.0 per cent among those from households in the poorest quintile.

Table 7.6 also shows that about 31.4 per cent of users of unimproved sanitation facility resorted to open defecation. Overall 25.0 per cent of the users of unimproved sanitation facilities did not share sanitation facility with others. There was hardly any difference in the percentage of users of a shared unimproved sanitation facility between household population in urban areas (7.8 per cent) and in rural areas (8.0 per cent). The proportion of users of unimproved sanitation facilities who used a facility not shared by other households was 25.7 per cent in urban areas compared to 23.4 per cent in rural areas. The proportion of household population who resorted to open defecation was 40.6 per cent among those with no education compared to 25.2 per cent among those with primary education and 10.7 per cent among those with secondary or higher level of education. There was a significant difference between household population in the richest and poorest quintiles who practiced open defecation. The proportion of household population who resorted to open defecation was 68.0 per cent among those from households in the poorest quintile compared to only 0.3 per cent among those from households in the richest quintile.

Disposal of child's faeces

Safe disposal of a child's faeces is disposing of the stool, by the child using a toilet or by rinsing the stool into a toilet or latrine. Disposal of faeces of children 0-2 years of age is presented in Table 7.7. Overall, the percentage of children whose stools were disposed of safely was 46.5 per cent. The percentages of children whose stools were disposed of safely using an improved and unimproved sanitation facility in the dwelling were 69.2 per cent and 65.7 per cent respectively. There was significant difference between rural and urban areas in the proportion of children whose stools were disposed of safely. The proportion of children whose stools were disposed of safely was 67.0 per cent in urban areas compared to 38.7 per cent in rural areas. There was also a significant difference between the proportion of children whose stools were disposed of safely among children whose mothers had no education (35.7 per cent) and among children whose mothers had secondary or higher level of education (75.7 per cent). Significant difference between those in households in the richest and poorest quintiles was noticed in terms of the proportion of children whose stools were disposed of safely. The proportion of children whose stools were disposed of safely was 75.7 per cent among those from households in the richest quintile compared to only 26.1 per cent among those from households in the poorest quintile.

The percentage of household population using both improved drinking water sources and improved sanitation facilities showed an increasing trend with the educational level of the household head. The percentage of household population using both improved drinking water sources and improved sanitation facilities was only 15.5 per cent in the case of households which had household head with no education compared to 22.7 per cent in the case of households which had head of households with primary education and 35.3 per cent in the case of households which had household head with secondary or higher level of education. The percentage of household population using both improved drinking water sources and improved sanitation facilities varied significantly with increase in household wealth. The percentage of household population using both improved drinking water sources and improved sanitation facilities was only 1.7 per cent in the case of the poorest households compared to 64.6 per cent in the case of the richest households.

The percentage of household population using both improved drinking water sources and improved sanitation facilities varied widely by State, ranging from 1.7 per cent in South Darfur to 67.3 per cent in Northern State. (Table 7.8 and Figure 7.7)

of women who have had a live birth before age 15 was 0.6 per cent in urban areas compared to 1.5 per cent in rural areas. The percentage of women who have had a live birth before age 15 was highest (2.1 per cent) among women age 35-39 years and the lowest (1.2 per cent) among women age 15-19 years. The percentage of women in urban areas who have had a live birth before age 15 was highest (2.7 per cent) among women age 30-34 years and the lowest (0.6 per cent) among women age 15-19 years. The percentage of women in rural areas who have had a live birth before age 15 was highest (2.2 per cent) among women aged 35-39 years and the lowest (1.4 per cent) among women aged 45-49 years

Percentage of women with a live birth before age 18 years: The SHHS2 findings indicated that about 14.0 per cent of women have had a live birth before age 18. There were some differences in percentage of women in urban and rural areas who have had a live birth by age 18. The percentage of women who have had a live birth before age 18 was 9.6 per cent in urban areas compared to 16.3 per cent in rural areas. The percentage of women who have had a live birth before age 18 was highest (14.0 per cent) among women age 20-24 years and the lowest (8.3 per cent) among women age 45-49 years. The percentage of women in urban areas who have had a live birth before age 18 was highest (14.3 per cent) among women age 30-34 years and the lowest (9.6 per cent) among women age 20-24 years. The percentage of women in rural areas who have had a live birth before age 18 was highest (16.3 per cent) among women aged 20-24 years and the lowest (6.6 per cent) among women aged 45-49 years.

**Table 8.2: Trends in early childbearing
Percentage of women who have had a live birth by age 15 and 18, by age groups, Sudan, 2010**

Contraception

Appropriate family planning is important to the health of women and children by: (i) preventing pregnancies that are too early or too late; (ii) extending the period between births; and (iii) limiting the number of children. Access by all couples to information and services to prevent pregnancies that are too early, too closely spaced, too late or too many is critical.

Table 8.3 provides information on the use of contraception. It indicates the percentage of women age 15-49 years currently married who are using (or whose partner is using) a contraceptive method. Current use of contraception was reported by 9.0 per cent of women currently married. The most popular method is the pill which is used by 6.3 per cent of married women in Sudan. The next most popular method was the use of injectables, which accounted for 0.9 per cent of married women. About 0.5 per cent of women reported use of the IUD. The other methods used include female sterilisation (0.3 per cent), Lactational Amenorrhoea Method (LAM) (0.3 per cent) and periodic abstinence/rhythm (0.3 per cent). Only 0.1 per cent reported the use of male condom. In all about 8.1 per cent of women reported the use of any modern method while about 0.9 per cent reported the use of any traditional method.

There was some differences in percentage of women age 15-49 years in urban and rural areas currently married who were using (or whose partner was using) a method of contraception. About 17.4 per cent of women in urban areas reported the use of a contraceptive method (any method) compared to only 5.4 per cent of women in rural areas. Adolescents are far less likely to use contraception than older women. Only about 4.8 per cent of married women aged 15-19 currently use a method of contraception compared to 9.2 per cent of 25-29 year olds and 11.4 per cent of 40-44 year old women.

Women's education level was found to be associated with contraceptive prevalence. For instance, the percentage of women age 15-49 years currently married and who were using (or whose partner was using) any method of contraception was only 2.4 per cent for women with no education compared to 11.6 per cent among women with primary education and 21.4 per cent among women with secondary or higher level of education. In addition to differences in contraceptive prevalence, the method mix varies by education. The percentage of women who were using (or whose partner was using) any modern method of contraception was only 2.4 per cent for women with no education compared to 10.4 per cent among women with primary education and 19.5 per cent among women with secondary or higher level of education. About 1.8 per cent of contraceptive users with no education used the pill while 14.5 per cent of contraceptive users with secondary or higher level of education used the pill.

The household wealth also appears to have an influence on the likelihood of the use of a contraceptive method. The percentage of women age 15-49 years currently married and who were using (or whose partner was using) a method of contraception was only 1.4 per cent among women belonging to households in the poorest households compared to 23.5 per cent for those belonging to households in the richest households. In addition to differences in contraceptive prevalence, the method mix varies by the household wealth. The percentage of women who were using (or whose partner was using) any modern method of contraception was only 1.2 per cent among women belonging to households in the poorest quintile compared to 21.8 per cent among women from households in the richest quintile. About 1.0 per cent of contraceptive users from households in the poorest quintile used the pill while 16.7 per cent of contraceptive users from households in the richest quintile used the pill.

The SHHS2 findings indicated that the percentage of women age 15 - 49 years (currently married) with unmet need for contraception for spacing and limiting were 18.4 per cent and 10.5 per cent respectively. The unmet need for contraception varied marginally by urban/rural areas. The unmet need for contraception for spacing was 17.5 per cent in the case of women in urban areas compared to 18.8 per cent for women in rural areas. The unmet need for contraception for limiting was 11.9 per cent in the case of women in urban areas compared to 9.8 per cent for women in rural areas.

The unmet need for contraception for spacing was highest (22.3 per cent) among women in South Darfur State and lowest (10.9 per cent) among women in West Darfur State while the unmet need for contraception for limiting was highest in South Darfur State at 13.4 per cent and the lowest in West Darfur State at 4.5 per cent.

The SHHS2 findings indicated that the 28.9 per cent of women age 15 - 49 years (currently married) have an unmet need for contraception for family planning

The unmet need for contraception varied marginally by urban/rural areas, by educational level of women and by household wealth. The unmet need for contraception was 29.3 per cent in the case of women in urban areas compared to 28.7 per cent for women in rural areas. The unmet need for contraception was 28.1 per cent in the case of women with no education compared to 31.8 per cent for women with primary education, and 26.7 per cent for women with secondary or higher level of education. The unmet need was 29.1 per cent among women belonging to households in the poorest quintile compared to 28.8 per cent among women from households in the richest quintile. The unmet need for contraception was highest (38.1 per cent) among women age 40-44 years and lowest (19.3 per cent) among women age 15-19 years.

The unmet need for contraception was highest in South Darfur State at 35.6 per cent and the lowest in West Darfur State at 15.4 per cent. (Figure 8.3)

Met need for contraception

Table 8.4 also shows the met need for contraception for spacing as well as met need for contraception for limiting. Met need for limiting includes women who are using a contraceptive method and who want no more children, are using male or female sterilization or declare themselves as infecund. Met need for spacing includes women who are using a contraceptive method and who want to have another child or undecided whether to have another child. The total of met need for spacing and limiting add up to the total met need for contraception.

The SHHS2 findings indicated that the percentage of women age 15 - 49 years (currently married) with met need for contraception for spacing and limiting were 6.8 per cent and 3.3 per cent respectively. The met need for contraception varied marginally by urban/rural areas, by educational level of women and by the level of household wealth. The met need for contraception for spacing was 12.7 per cent in the case of women in urban areas compared to 4.2 per cent for women in rural areas. The met need for contraception for limiting was 6.3 per cent in the case of women in urban areas compared to 1.9 per cent for women in rural areas.

The met need for contraception for spacing was only 2.3 per cent in the case of women with no education compared to 8.3 per cent for women with primary education, and 16.1 per cent for women with secondary or higher level of education. The met need for contraception for limiting was only 1.4 per cent in the case of women with no education compared to 4.2 per cent for women with primary education, and 6.4 per cent for women with secondary or higher level of education. The met need for contraception for spacing was 1.5 per cent among women belonging to households in the poorest quintile compared to 15.3 per cent among women from households in the richest quintile. The met need for contraception for limiting was 0.5 per cent among women belonging to household in the poorest quintile compared to 9.0 per cent among women from households in the richest quintile. The met need for contraception for spacing was highest (8.5 per cent) among women age 25-29 years and lowest (1.5 per cent) among women age 45-49 years while the met need for contraception for limiting was highest (8.3 per cent) among women age 40-44 years and lowest (0.3 per cent) among women age 15-19 years.

The met need for contraception for spacing was highest (14.1 per cent) among women in Khartoum State and lowest (2.1 per cent) among women in Kassala State. The met need for contraception for limiting was highest in Northern State at 9.3 per cent and the lowest in North Darfur State at 0.7 per cent.

Demand for contraception

Using information on contraception and unmet need, the percentage of demand for contraception satisfied was also estimated from the SHHS2 data. Percentage of demand satisfied is defined as the proportion of women currently married or in a marital union who are currently using contraception, of the total demand for contraception. The total demand for contraception includes women who currently have an unmet need (for spacing or limiting), plus those who are currently using contraception.

The SHHS2 findings indicated that the percentage of demand for contraception satisfied was 25.9 per cent. The percentage of demand for contraception satisfied varied significantly by urban/rural areas, by educational level of women and by the economic status of the households. The percentage of demand for contraception satisfied was 39.4 per cent in the case of women in urban areas compared to 17.6 per cent for women in rural areas.

The percentage of demand for contraception satisfied was only 12.0 per cent in the case of women with no education compared to 28.3 per cent for women with primary education, and 45.3 per cent for women with secondary or higher level of education. The percentage of demand for contraception satisfied was only 6.6 per cent among women belonging to households in the poorest quintile compared to 45.7 per cent among women from households in the richest quintile.

The percentage of demand for contraception satisfied was highest (22.3 per cent) among women in Northern State and the lowest (9.5 per cent) among women in South Darfur State.

Antenatal Care

The antenatal period presents important opportunities for reaching pregnant women with a number of interventions that may be vital to their health and well-being and that of their infants. Better understanding of foetal growth and development and its relationship to the mother's health has resulted in increased attention to the potential of antenatal care as an intervention to improve both maternal and newborn health. For example, if the antenatal period is used to inform women and families about the danger signs and symptoms and about the risks of labour and delivery, it may provide the route for ensuring that pregnant women do, in practice, deliver with the assistance of a skilled health care provider. The antenatal period also provides an opportunity to supply information on birth spacing, which is recognized as an important factor in improving infant survival. Tetanus immunization during pregnancy can be life-saving for both the mother and infant. The prevention and treatment of malaria among pregnant women, management of anaemia during pregnancy and treatment of STIs can significantly improve foetal outcomes and improve maternal health. Adverse outcomes such as low birth weight can be reduced through a combination of interventions to improve women's nutritional status and prevent infections (e.g., malaria and STIs) during pregnancy. More recently, the potential of the antenatal period as an entry point for HIV prevention and care, in particular for the prevention of HIV transmission from mother to child, has led to renewed interest in access to and use of antenatal services.

WHO recommends a minimum of four antenatal visits based on a review of the effectiveness of different models of antenatal care. The WHO guidelines are specific on the content of antenatal care visits, which include: (i) Blood pressure measurement; (ii) Urine testing for bacteriuria and proteinuria; (iii) Blood testing to detect syphilis and severe anemia; and (iv) Weight/height measurement.

Antenatal care providers

Table 8.5: provides details of the antenatal care provider, i.e. the type of personnel providing antenatal care. It indicates the percent distribution of women aged 15-49 who gave birth in the two years preceding the survey by type of personnel providing antenatal care. The findings of the SHHS indicated that 74.3 per cent of women aged 15-49 years who gave birth in the two years preceding the SHHS2 received antenatal care (ANC) at least once by skilled personnel; Doctor, Nurse Midwife, Midwife and Health Visitor.

The percentage of women who received ANC was found to be influenced by the women's education level and the level of household wealth: only 63.3 per cent of women with no formal education received ANC at least once by skilled personnel, while 81.9 per cent of women with primary education and 91.5 per cent of women with secondary or higher level of education received ANC at least once by skilled personnel. The percentage of women who received no ANC was only 8.7 in the case of women with secondary or higher education compared to 34.4 for women with no education. The percentage of women who received ANC was higher among women from households in the richest quintile than those from households in the poorest quintile, being only 62.7 per cent among women from households in the poorest quintile compared to 91.7 per cent among women from households in the richest quintile. The percentage of women who received no ANC was only 8.0 in the case of women from households in the richest quintile compared to 34.9 among women from households in the poorest quintile.

In the country as a whole, about a quarter of women (25.7 per cent) age 15-49 years who gave birth in the two years preceding the survey received no antenatal care from qualified health personnel (a doctor, nurse midwife, health visitor or midwife). About 46.9 per cent of women received ANC from a medical doctor, 3.6 per cent received ANC from a nurse midwife, 5.4 per cent from a health visitor and 18.4 per cent from a midwife.

Antenatal care visits

Table 8.6: provides information relating to the percentage of women who had a live birth during the last two years preceding the survey by number of antenatal care visits by any provider. It indicates the number of antenatal care visits during the last pregnancy during the two years preceding the survey, regardless of provider. UNICEF and WHO recommend a minimum of at least four antenatal care visits during pregnancy.

The SHHS2 data indicated that almost seven in ten mothers (70.0 per cent) who had a live birth during the last two years preceding the survey received antenatal care more than once by any provider and about half of mothers received antenatal care at least four times (47.1 per cent). Mothers living in urban areas are more likely than those living in rural areas to receive ANC four or more times. The percentage of women who had a birth during the two years preceding the SHHS2 and who had four or more antenatal care visits was only 39.7 per cent in the case of women in rural areas compared to 66.8 per cent among women in urban areas.

Mothers with no formal education and those from households in the poorest quintile are less likely than more advantaged mothers to receive ANC four or more times. For instance, the percentage of women who had a birth during the two years preceding the SHHS2 and who had four or more antenatal care visits was only 34.1 in the case of women with no education compared to 53.4 per cent among women with primary education and 72.1 per cent among women with secondary or higher level of education. Similarly, only 31.7 per cent of the women from households in the poorest quintile reported four or more antenatal care visits by any health provider compared to 73.7 per cent among those from households in the richest quintile.

Figure 8.5: Antenatal care visits
Percentage of women who had a live birth during the two years preceding the survey and had four or more antenatal care visits, Sudan, 2010

Content of antenatal care

The types of services pregnant women received are shown in Table 8.8. Among those women who have given birth to a child during the two years preceding the survey, 55.8 per cent reported that a blood sample was taken during antenatal care visits, 57.7 per cent reported that their blood pressure was checked, and 56.7 per cent reported that urine specimen was taken.

Table 8.8 provides information relating to assistance during delivery. It indicates the percent distribution of women age 15-49 that had a live birth in the two years preceding the survey by perso

Early childhood care and education

Participation in an organised learning or child education programme is important for the overall social, emotional and intellectual development of children. Table 9.2 shows the percentage of children age 36-59 months who were attending some form of organized early childhood care and education programme at the time of the SHHS2. The data indicated that only 20.4 per cent of children age 36-59 months was attending some form of organized early childhood care and education programme at the time of SHHS2. The percentage of children age 36-59 months who were attending some form of organized early childhood care and education programme was higher among children in urban areas (37.4 per cent) than that among children in rural areas (13.9 per cent). Very little gender differential exists, the percentage of boys and girls who were attending some form of organized early childhood education programme being 19.9 per cent and 20.9 per cent respectively.

The proportion of children attending some form of organised early childhood care and education programme was lower among children age 36-47 months (14.9 per cent) than that among children age 48-59 months (27.6 per cent). The proportion of children attending some form of organised early childhood care and education programme varies by the education level of mothers. The proportion of children attending some form of organised early childhood care and education programme was higher among children who had mothers with secondary or higher level of education (37.6 per cent) than that for children who had mothers with primary education (23.8 per cent) and that among children who had mothers with no formal education (14.7 per cent). The proportion of children attending some form of organised early childhood care and education programme also varied by their household wealth. The proportion of children attending some form of organised early childhood care and education programme was much higher among those belonging to households in the richest quintile (48.1 per cent) than those belonging to households in the poorest quintile (9.8 per cent).

School Readiness

Participation in pre-school education programme is considered important for the readiness of children to attend primary school. Pre-school education in Sudan, offered through Kindergartens for children age 4-5 years, is neither free nor compulsory.

Table 9.3 shows the proportion of children attending the first grade of primary school who attended pre-school in the previous year preceding the SHHS2.

Overall, 45.3 per cent of children who were attending the first grade of primary school at the time of the SHHS had attended pre-school the previous year. The proportion among females was slightly higher (46.5 per cent) than males (44.3 per cent). Almost two-thirds (65.0 per cent) of children in urban areas had attended pre-school the previous year compared to only 36.8 per cent among children living in rural areas. Socio-economic status appears to have a positive impact in terms of the proportion of children who had attended pre-school the previous year. While the percentage of children attending first grade who attended pre-school in the previous year was 75.8 per cent among children living in the richest households, the percentage was only 17.1 per cent among children belonging to the poorest households.

Primary School Participation

Primary school entry (Net intake rate in primary education): Table 9.4 provides information regarding the net intake rate in primary education, i.e. percentage of children of primary school entry age entering grade I in primary school. Of children who were of primary school entry age (age 6) in Sudan, about 46.0 per cent of them were attending the first grade of primary school at the time of the SHHS2. Of male children who were of primary school entry age, 46.9 per cent of them were attending the first grade of primary school compared to 45.1 per cent of female children of primary school entry age.

Children’s participation in primary education was timelier in urban areas than in rural areas. The net intake rate in primary education was 67.1 per cent in urban areas compared to 37.9 per cent in rural areas. While the net intake rate in primary education was 0.0 per cent in the case of children of mothers who had no education, the rates were 90.9 per cent in the case of children whose mothers had primary education, and 93.6 per cent in the case of children whose mothers had secondary or higher levels of education. It was observed that the net intake rates in primary education varied widely with household wealth. The proportion of children of primary school entry age entering grade I in primary school was around 81.8 per cent in the case of children belonging to households in the richest quintile, while it was only 23.2 per cent among children belonging to households in the poorest quintile.

Net primary school attendance ratio

Table 9.5 provides the net primary school attendance ratio, i.e. percentage of children of primary school age who are attending primary or secondary school⁷. The official primary school-age group in Sudan is 6-13 years.

The net primary school attendance ratio shows the extent of participation in education of children belonging to the official primary school-age group. A high net primary school attendance ratio denotes a high degree of participation in education of the primary school-age population while a low net primary school attendance ratio indicates a low degree of participation of the primary school-age population. Achieving a net primary school attendance ratio that is closer to 100 per cent is a key target for achieving the goal of universal primary education. Where the net primary school attendance ratio is less than 100 per cent, the complement (i.e., 100 per cent minus the net primary school attendance ratio value) provides a measure of proportion of out-of-school primary school-age children.

The SHHS2 data indicate that about 71.8 per cent of children of primary school age were attending school at the time of the survey. This means that about 28.2 per cent of the children were out of school when they were expected to be participating in primary education. The percentage of children of primary-school age attending school at the time of the survey was highest (81.9 per cent) among children aged 10 years and lowest among children aged 6 years (49.4 per cent).

Sex differentials in net primary school attendance ratios do exist; the net primary school attendance ratio for boys being 74.2 per cent compared to 69.4 per cent for girls. The net primary school attendance ratio for boys was highest among those aged 10 years (86.3 per cent) and lowest among those aged 6 years (50.8 per cent). In the case of girls also, the net primary school attendance ratio

⁷ Ratios presented in this table are "adjusted" since they include not only primary school attendance, but also secondary school attendance in the numerator.

ratio for girls in urban areas was 87.0 per cent compared to 62.5 per cent in the case of girls in rural areas.

The education level of the mother appears to have an influence on the net primary school attendance ratio. While the net primary school attendance ratio for children whose mothers had no education was only 0.2 per cent, it was 95.2 per cent for children whose mothers had primary education, and 95.2 per cent in the case of children whose mothers had secondary or higher levels of education. Similarly, while the net primary school attendance ratio for male children whose mothers had no education was only 0.3 per cent, it was 95.4 per cent for male children whose mothers had primary education, and 95.0 per cent in the case of male children whose mothers had secondary or higher levels of education. While the net primary school attendance ratio for female children whose mothers had no education was only 0.1 per cent, it was 95.0 per cent for female children whose mothers had primary education, and 97.2 per cent in the case of female children whose mothers had secondary or higher levels of education.

The household wealth also appears to have an influence on the net primary school attendance ratio. The net primary school attendance ratio was only 50.1 per cent among children belonging to households in the poorest quintile compared to 96.7 per cent among children from households in the richest quintile. The net primary school attendance ratio was only 56.1 per cent among boys belonging to households in the poorest quintile compared to 96.6 per cent among those from households in the richest quintile. Similarly, the net primary school attendance ratio was only 44.4 per cent among girls belonging to households in the poorest quintile compared to 97.6 per cent among girls from households in the richest quintile.

There were also considerable variations in the net primary school attendance ratios among states. The net primary school attendance ratio ranged from 91.6 per cent in Northern State to 55.7 per cent in Kassala State. There also exist considerable variations among States in terms of the net primary school attendance ratio of boys, ranging from 91.6 per cent in Northern State to 56.2 per cent in Blue Nile State. Noticeable variations also exist among States in net primary school attendance ratio of girls, ranging from 91.7 per cent in Northern State to 48.8 per cent in West Darfur State.

Figure 9.5: Primary school attendance
Percentage of children of primary school age attending primary or secondary school (Net primary school attendance ratio - adjusted), Sudan, 2010

Secondary School Attendance

The percentage of children of secondary school age attending secondary school or higher level institutions (adjusted net attendance ratio), and percentage of secondary school-age children attending primary school, are presented in Table 9.6⁸. The official secondary school-age group in Sudan is 14-16 years.

Table 9.6: Secondary school attendance
Percentage of children of secondary school age attending secondary school or higher (adjusted net secondary school attendance ratio), and percentage of children attending primary school, Sudan, 2010

	Male			Female			Total		
	Net attendance ratio (adjusted) [1]	Percent attending primary school	Number of children	Net attendance ratio (adjusted) [1]	Percent attending primary school	Number of children	Net attendance ratio (adjusted) [1]	Percent attending primary school	Number of children
Northern	44.3	33.9	42	60.2	20.5	43	52.3	27.1	85
River Nile	45.7	25.6	76	50.7	16.8	75	48.2	21.2	151
Red Sea	16.9	50.5	60	25.5	32.3	49	20.8	42.3	110
Kassala	18.4	36.0	146	18.8	23.2	132	18.6	29.9	278
Gadarif	22.0	50.5	80	12.1	26.4	118	16.1	36.1	198
Khartoum	50.6	29.5	433	58.3	22.5	362	54.1	26.3	795

⁸ Ratios presented in this table are "adjusted" since they include not only secondary school attendance, but also attendance to higher levels in the numerator.

The education level of the mother appears to have an influence on the NAR for secondary school-age children. While the net secondary school attendance ratio for children whose mothers had no education was only 10.5 per cent, it was 95.1 per cent among children whose mothers had secondary or higher level of education. Similarly, while the net secondary school attendance ratio for boys whose mothers had no education was only 11.8 per cent, it was 94.1 per cent among boys whose mothers had secondary or higher levels of education. Similarly, while the net secondary school attendance ratio for girls whose mothers had no education was only 9.7 per cent, it was 96.1 per cent among girls whose mothers had secondary or higher levels of education.

The household wealth also appears to have an influence on the net secondary school attendance ratio. The net secondary school attendance ratio was only 6.5 per cent among children belonging to households in the poorest quintile compared to 69.2 per cent among children from the households in the richest quintile. The net secondary school attendance ratio was only 7.8 per cent among boys belonging to households in the poorest quintile compared to 65.3 per cent among boys from households in the richest quintile. Similarly, the net secondary school attendance ratio for girls was only 8.1 per cent among those belonging to households in the poorest quintile compared to 73.1 per cent among those from households in the richest quintile.

There were also considerable variations in the net secondary school attendance ratios among States. The net secondary school attendance ratios ranged from 54.1 per cent in Khartoum State to 10.9 per cent in West Darfur State. There also exist considerable variations among states in terms of the net secondary school attendance ratios for boys, ranging from 50.6 per cent in Khartoum State to 10.1 per cent in West Darfur State. Noticeable variations also exist among States in net secondary school attendance ratio for girls, ranging from 60.2 per cent in Northern State to 10.0 per cent in West Darfur State.

Secondary school-age children attending primary school

The percentage of secondary school-age children attending primary school is presented in Table .6. About one-third (34.3 per cent) of secondary school age-children were found to be attending primary

Figure 9.8: Primary school completion rates
Percentage of children (of any age) attending the last grade of primary school (excluding repeaters) to total number of children of primary school completion age (i.e. 13 years), Sudan, 2010

Transition rate to secondary education

The SHHS findings indicated that only 77.8 per cent of the children that completed successfully the last grade of primary school were found at the time of the survey to be attending the first grade of secondary school (Table 9.8). The transition rate to secondary school (percentage of the children that completed successfully the last grade of primary school attending the first grade of secondary school) was 74.9 per cent for boys compared to 80.9 per cent for girls. The transition rate to secondary school was 79.0 per cent for children in urban areas compared to 76.9 per cent for children in rural areas.

The household wealth appears to have a positive impact on the transition rate to secondary school. The transition rate to secondary education was 83.8 per cent for children from households in the richest quintile compared to 68.0 per cent among children from households in the poorest quintile.

There were considerable variations in the transition rates to secondary education among States. The transition rates to secondary education ranged from 90.1 per cent in Kassala State to 59.2 per cent in South Kordofan State.

Education gender parity

The ratio of girls to boys attending primary and secondary education is provided in Table 9.9. These ratios are better known as the Gender Parity Index (GPI). Notice that the ratios included here are obtained from net attendance ratios rather than gross attendance ratios. The last ratios provide an erroneous description of the GPI mainly because in most of the cases the majority of over-aged children attending primary education tend to be boys.

Table 9.9 shows that gender parity at the primary stage of education was 0.94, indicating that there is difference in the net primary school attendance ratios of girls and boys. The disadvantage of girls at the primary stage of education was particularly pronounced in some of the States such as Kassala (GPI: 0.80), Gadarif (GPI: 0.88), Sinnar (GPI: 0.88), West Darfur: 0.77) and South Darfur (GPI: 0.85). The GPI ranged between 1.11 in Red Sea State to 0.77 in West Darfur. The disadvantage of girls at the primary stage of education was also pronounced among children living in rural areas and in households in the poorest quintile. The GPI in rural areas was 0.91 compared to 1.0 in urban areas. The GPI for children belonging to the households in the richest quintile was 1.0 compared to 0.79 for children belonging to households in the poorest quintile.

The SHHS2 indicator relating to birth registration is the proportion of children under age five whose birth are reported registered. The SHHS2 data indicated that the births of 59.3 percent of under-five children in Sudan were reported registered on the reference date of the survey. Of the children under age five whose birth was not registered, mothers/caretakers of 26.3 per cent of these children knew how to register birth. The birth registration rates ranged from 94.3 percent in Northern State to 23.3 percent in West Darfur State.

Birth registration rates were highest among children age 12-23 months at 62.6 per cent and lowest among children age 36-47 months at 56.8 per cent. Birth registration rate among children aged 0-11 months was 57.0 per cent. There were some variations in birth registration between male and female children, the birth registration rate for male and female being 61.3 per cent and 57.2 per cent respectively. However, there were significant variations in birth registration between urban and rural areas; the birth registration rate in rural areas being only 49.7 per cent in rural areas compared to 84.5 per cent in urban areas.

Birth registration appears to increase with mother's educational level and the household wealth: birth registration rate among children of mothers with no education was only 44.5 per cent compared to 72.4 per cent for children of mothers with primary education and 90.5 per cent for children of mothers with secondary or higher level of education. Birth registration rate among children from households in the poorest quintile was only 26.0 per cent compared to 98.0 per cent among those from households in the richest quintile (Figure 10.1A)

Early Marriage and Polygamy

Marriage before the age of 18 is a reality for many young girls. According to UNICEF's worldwide estimates, over 64 million women age 20-24 were married/in union before the age of 18. Factors that influence child marriage rates include: the state of the country's civil registration system, which provides proof of age for children; the existence of an adequate legislative framework with an accompanying enforcement mechanism to address cases of child marriage; and the existence of customary or religious laws that condone the practice.

In many parts of the world parents encourage the marriage of their daughters while they are still children in hopes that the marriage will benefit them both financially and socially, while also relieving financial burdens on the family. In actual fact, child marriage is a violation of human rights, compromising the development of girls and often resulting in early pregnancy and social isolation, with little education and poor vocational training reinforcing the gendered nature of poverty. The right to 'free and full' consent to a marriage is recognized in the Universal Declaration of Human Rights - with the recognition that consent cannot be 'free and full' when one of the parties involved is not sufficiently mature to make an informed decision about a life partner.

The Convention on the Elimination of all Forms of Discrimination against Women mentions the right to protection from child marriage in article 16, which states: "The betrothal and the marriage of a child shall have no legal effect, and all necessary action, including legislation, shall be taken to specify a minimum age for marriage..." While marriage is not considered directly in the Convention on the Rights of the Child, child marriage is linked to other rights - such as the right to express their views freely, the right to protection from all forms of abuse, and the right to be protected from harmful traditional practices - and is frequently addressed by the Committee on the Rights of the Child. Other international agreements related to child marriage are the Convention on Consent to Marriage, Minimum Age for Marriage and Registration of Marriages and the African Charter on the Rights and Welfare of the Child and the Protocol to the African Charter on Human and People's Rights on the Rights of Women in Africa. Child marriage was also identified by the Pan-African Forum against the Sexual Exploitation of Children as a type of commercial sexual exploitation of children.

Young married girls are a unique, though often invisible, group. Required to perform heavy amounts of domestic work, under pressure to demonstrate fertility, and responsible for raising children while still children themselves, married girls and child mothers face constrained decision-making and reduced life choices. Boys are also affected by child marriage but the issue impacts girls in far larger numbers and with more intensity. Cohabitation - when a couple lives together as if married - raises the same human rights concerns as marriage. Where a girl lives with a man and takes on the role of

The household wealth also appears to have an influence on the incidence of early marriage. The percentage of women aged 15-19 years currently married was only 8.4 per cent among women from households in the richest quintile compared to 31.9 per cent among women belonging to households in the poorest quintile. The percentage of young women aged 15-19 years currently married ranged from 9.4 in Northern State to 43.3 in West Darfur State.

Women in Polygamous marriage

The information relating to the percentage of women in a Polygamous marriage is provided in Table 10.2. Nationwide, about 20.0 per cent of women age 15-49 years were in Polygamous marriage. This percentage was lower among women in urban areas (15.3 per cent) than that among women in rural areas (22.1 per cent).

The incidence of polygamy appears to be linked to women's education level and the household wealth. While the percentage of women age 15-19 years in Polygamous marriage was 27.5 in the case of women with no formal education, it was only 14.9 among women with primary education and 9.3 among women with secondary or higher level of education. The percentage of women age 15-49 years in Polygamous marriage was only 9.7 in the case of women belonging to households in the richest quintile compared to 31.0 among women belonging to households in the poorest quintile. The age of the woman also appears to be a factor: the percentage of women in Polygamous marriage was lowest (10.8) among women in the age 15-19 years compared to 26.1 among women aged 35-39 years, 26.0 among women aged 40-44 years and 25.7 among women aged 45-49 years.

The percentage of women age 15-49 years in Polygamous marriage ranged from 5.7 per cent in Northern State to 41.8 per cent in West Darfur State.

Trends in early marriage

Table 10.3 presents the proportion of women who were first married before age 15 and 18 years by residence and age groups. Examining the percentages of women married before age 15 and 18 years by different age groups allow us to see the trends in early marriage over time. There seems to be a positive trend in terms of reduction in the percentage of women married before age 15 over time.

Overall, the percentage of women married before age 15 was only 4.9 per cent among women in the age group 15-19 years compared to 7.2 per cent among women in the age group 20-24 years, 10.3 per cent among women in the age group 25-29 years, 10.6 per cent among women in the age group 30-34 years, 12.6 per cent among women in the age group 35-39 years, 13.2 per cent among women in the age group 40-44 years and 15.5 per cent among women in the age group 45-49 years. The percentage of women married before age 18 was 32.9 per cent among women in the age group 20-24 years compared to 36.3 per cent among women age 25-29 years, 37.0 per cent among women age 30-34 years, 40.6 per cent among women age 35-39 years, 43.1 per cent among women age 40-44 years and 43.2 per cent among women age 45-49 years.

A similar trend was observed in the case of women in urban areas who were married before age 15. The percentage of women in urban areas who were married before age 15 was only 1.9 per cent among women in the age group 15-19 years compared to 4.7 per cent among women in the age group 20-24 years, 6.1 per cent among women in the age group 25-29 years, 8.9 per cent among women in the age group 30-34 years, 11.3 per cent among women in the age group 35-39 years, 10.4 per cent among women in the age group 40-44 years and 14.7 per cent among women in the age group 45-49 years. The percentage of women in urban areas who were married before age 18 was 21.6 per cent among women in the age group 20-24 years compared to 26.5 per cent among women age 25-29 years, 30.3 per cent among women age 30-34 years, 32.4 per cent among women age 35-39 years, 34.3 per cent among women age 40-44 years and 41.9 per cent among women age 45-49 years.

Table 10.3: Trends in early marriage					
Percentage of women who were first married or entered into a marital union before age 15 and 18, by residence and age groups, Sudan, 2010					
Area of residence	Age	Percentage of women married before age 15	Number of women	Percentage of women married before age 18	Number of women
URBAN	15-19	1.9	1240	.	0

The percentage of women in rural areas who were married before age 15 was only 6.5 per cent among women in the age group 15-19 years compared to 8.6 per cent among women in the age group 20-24 years, 12.1 per cent among women in the age group 25-29 years, 11.5 per cent among women in the age group 30-34 years, 13.2 per cent among women in the age group 35-39 years, 14.7 per cent among women in the age group 40-44 years and 16.0 per cent among women in the age group 45-49 years. The percentage of women in rural areas who were married before age 18 was 39.0 per cent among women in the age group 20-24 years compared to 40.7 per cent among women aged 25-29 years, 40.6 per cent among women age 30-34 years, 44.7 per cent among women age 35-39 years, 48.1 per cent among women age 40-44 years and 43.8 per cent among women age 45-49 years.

Female Genital Mutilation/Cutting (FGM/C)

Female genital mutilation/cutting (FGM/C) is the partial or total removal of the female external genitalia or other injury to the female genital organs. FGM/C is always traumatic with immediate complications including excruciating pain, shock, urine retention, ulceration of the genitals and injury to adjacent tissue. Other complications include septicæmia, infertility, obstructed labour, and even death. The procedure is generally carried out on girls between the ages of five and 15 years. It is often performed by traditional practitioners, including midwives. It is generally performed by traditional midwives, nurses, midwives and doctors.

FGM/C is a fundamental violation of human rights. In the absence of any perceived medical necessity, it subjects girls and women to health risks and has life-threatening consequences. Among those rights violated are the rights to the highest attainable standard of health and to bodily integrity. Furthermore, it could be argued that girls (under 18) cannot be said to give informed consent to such a potentially damaging practice as FGM/C.

[1] SHHS indicator 7.6						

FGM/C prevalence appears to be linked to both the education level of the women and the economic level of the household. While the percentage of women aged 15-49 years who had any form of FGM/C was 55.5 per cent among women with no formal education, it was 76.1 per cent for women with primary education and 91.5 per cent for women with secondary or higher level of education. The percentage of women age 15-49 years who had some form of female genital mutilation was 72.6 per cent for women from households in the richest quintile compared to 63.0 per cent for women from households in the poorest quintile.

The proportion of women age 15-49 years reported to have undergone any form of female genital mutilation/cutting varied by State, ranging from 46.0 per cent in West Darfur State to 83.8 per cent in Northern State.

The percentage of girls and women subjected to FGM/C by person who performed the FGM/C appears to be linked to the education level of the women. The proportion of girls who had been subjected to FGM/C by traditional midwives was 41.6 per cent among women who had no formal education compared to 45.3 per cent for women with primary education and 41.6 per cent for women with secondary and higher level of education. The proportion of girls/women who had been subjected to FGM/C by a qualified nurse or midwife was 24.6 per cent among women who had no formal education compared to 52.8 per cent for women with primary education and 56.2 per cent for women with secondary and higher level of education.

The percentage of girls and women subjected to FGM/C by person who performed the FGM/C appears also to be linked to household wealth. The proportion of girls who had been subjected to FGM/C by traditional midwives was 70.9 per cent among women from households in the poorest quintile compared to 41.6 per cent among women from households in the richest quintile. The proportion of girls who had been subjected to FGM/C by a qualified nurse or midwife was 25.8 per cent among women from households in the poorest quintile compared to 52.7 per cent among women households in the richest quintile.

The proportion of girls who had been subjected to FGM/C by a traditional midwife or by a qualified nurse/midwife varies by State. The proportion of girls who had been subjected to FGM/C by traditional midwives ranged from 36.4 per cent in Northern State to 79.3 per cent in Red Sea State. The proportion of girls who had been subjected to FGM/C by a qualified nurse or midwife ranged from 17.6 per cent in Red Sea State to 62.8 per cent in Northern State.

Women intending to perform FGM/C their daughters

Table 10.6 presents information relating to the proportion of ever-married women age 15-49 intending or not intending to perform cutting gentile (FGM/C) their daughters.

The SHHS2 findings indicated that about 48.0 per cent of ever married women age 15-49 years intended to perform cutting gentile their daughters while 33.6 per cent indicated that they did not intend to perform cutting gentile their daughters. This percentage was highest (55.9 per cent) among women in the age group 35-39 years and the lowest (30.5 per cent) among young girls/women in the age group 15-19 years. The proportion of women who indicated they did not intend to perform cutting gentile their daughters was highest (39.2 per cent) among women in the age group 40-44 years and the lowest (20.8 per cent) among women in the age group 15-19 years.

The proportion of ever-married women age 15-49 years intending to perform cutting genitalia their daughters ranged from 27.4 per cent in Khartoum State to 71.3 per cent in South Darfur State while the proportion of women not intending to perform cutting genitalia their daughters was lowest at 12.7 per cent in West Darfur State and highest at 50.0 per cent in Khartoum State.

Attitude of women age 15-49 years towards FGM/C

Table 10.7 presents the attitudes of women age 15-49 years towards whether the practice of FGM/C should be continued or discontinued.

Regarding opinion as to whether the practice should be continued or discontinued, 42.3 per cent of women thought it should be continued while 53.0 per cent believed it should be discontinued. The attitude of women towards whether the practice of FGM/C should be continued or discontinued appears to be linked to the woman's education level and the household wealth. Approval of the continuation of the practice was highest among women with no formal education (59.7 per cent) than those with primary education (44.0 per cent) and those with secondary or higher level of education (17.3 per cent). Disapproval of the continuation of the practice was higher among women with secondary and higher level of education (79.8 per cent) than those with primary education (51.2 per cent) and those with no formal education (34.3 per cent). Women from households in the richest quintile are less likely to approve of the continuation of the practice than women from households in the poorest quintile. Approval of the continuation of the practice was higher among women from households in the poorest quintile (68.6 per cent) than those from households in the richest quintile (20.7 per cent). Disapproval of the continuation of the practice was highest among women from households in the richest quintile (75.9 per cent) than those from households in the poorest quintile (26.1 per cent).

Attitude of ever married women age 15-49 years towards FGM/C

Table 10.8 presents the attitudes of ever married women age 15-49 years towards whether the practice of FGM/C should be continued or discontinued. Regarding opinion as to whether the practice should be continued or discontinued, 48.1 per cent of ever married women age 15-49 years thought it should be continued while 47.0 per cent believed it should be discontinued.

The percentage of ever married women who believed that the practice of FGM/C should be continued was highest among those in the age group 15-19 years (51.1 per cent) and lowest among those in the age group 40-44 years (43.4 per cent). The percentage of ever married women who believed that the practice of FGM/C should be discontinued was highest among those in the age group 40-44 years (52.6 per cent) and lowest among those in the age group 20-24 years (45.0 per cent).

The attitude of ever married women towards whether the practice of FGM/C should be continued or discontinued appears to be linked to the woman's education level and the household wealth. Approval of the continuation of the practice was higher among ever married women with no formal education (61.3 per cent) than among those with primary education (46.3 per cent) and those with secondary or higher level of education (19.0 per cent). Disapproval of the continuation of the practice was higher among ever married women with secondary and higher level of education (77.6 per cent) than among those with primary education (48.9 per cent) and those with no formal education (33.2 per cent). Ever married women from households in the richest quintile are less likely to approve of the continuation of the practice of female circumcision than women from households in the poorest quintile. Approval of the continuation of the practice was higher among ever married women from households in the poorest quintile (72.8 per cent) than among those from households in the richest quintile (24.9 per cent).

cent).

Attitudes Toward Domestic Violence

A number of questions were asked of women age 15-49 years to assess their attitudes toward whether husbands are justified to hit or beat their wives/partners in certain circumstances. These questions were asked to have an indication of the cultural beliefs that tend to be associated with the prevalence of violence against women by their husbands/partners. The main assumption here is that women that agree with the statements indicating that husbands/partners are justified to beat their wives/partners under the situations described in reality tend to be abused by their own husbands/partners.

The main SHHS2 indicator used to assess women's attitude towards domestic violence is as follows:

- *Attitude towards domestic violence:* Proportion of women age 15-49 years who state that a husband/partner is justified in hitting or beating his wife in at least one of the following circumstances: (i) she goes out without telling him, (ii) she neglects the children, (iii) she argues with him, (iv) she refuses sex with him, and (v) she burns the food.

The responses to SHHS2 questions are indicated in Table 10.10. Overall, 47.0 per cent of women in Sudan feel that their husband/partner has a right to hit or beat them for at least one of a variety of reasons. Women who approve their partner's violence, in most cases, agree and justify violence in instances when they neglect their children (35.2 per cent), or if they demonstrate their autonomy, for e.g. go out without telling their husbands or argue with them (31.5 per cent) or argue with the husband (30.1 per cent). Over one-fourth (27.7 per cent) of women believe that their partner has a right to hit or beat them if they refuse to have sex with him, while around one-fourth (26.7 per cent) of women believe that their partner has a right to hit or beat them or if they burn the food. Acceptance is more

present among those living in households on the poorest quintile, less educated, and also currently married women.

Table 10.10: Attitudes toward domestic violence
Percentage of women age 15-49 years who believe a husband is justified in beating his wife/partner in various circumstances, Sudan, 2010

[1] SHHS indicator 7.11

The attitude toward domestic violence appears to be linked to the women's education level and the household wealth. The percentage of women age 15-49 years who believe a husband is justified in beating his wife/partner in various circumstances was higher among women with no formal education

(59.8 per cent) than among those with primary education (47.0 per cent) and those with secondary or higher level of education (31.7 per cent). Women from households in the richest quintile are less likely to approve of the practice of beating wife/partner in various circumstances than women from households in the poorest quintile. Approval of the practice was highest among women from households in the poorest quintile (68.8 per cent) than those from households in the richest quintile (28.9 per cent).

The percentage of women age 15-49 years who believe that a husband is justified in beating his wife/partner in various circumstances was lowest among women in the age group 45-49 years (44.0 per cent) and highest among women in the age group 15-19 years (51.9 per cent). The percentage of women age 15-49 years who believe that a husband is justified in beating his wife/partner in various circumstances was higher among women in rural areas (51.5 per cent) than that among women in urban areas (38.2 per cent). The percentage of women age 15-49 years who believed that a husband was justified in beating his wife/partner in various circumstances was higher among formerly married women (51.0 per cent) than that among women currently married (48.3 per cent) and that among women never married (43.5 per cent).

The percentage of women age 15-49 years who believed that a husband was justified in beating his wife in various circumstances was lowest in Red Sea State (19.2 per cent) and highest in West Darfur State (83.6 per cent).

Children's Living Arrangements and Orphanhood

Children who are orphaned or in vulnerable households may be at increased risk of neglect or exploitation if the parents are not available to assist them. Children are considered as orphaned if they have one or both of their parents dead. Monitoring the variations in different outcomes for orphans and vulnerable children and comparing them to their peers gives us a measure of how well communities and governments are responding to their needs.

Children's living arrangements

Table 10.11 provides information relating to children's living arrangements and orphan hood. It indicates the percentage of children aged 0-17 years according to living arrangements, percentage of children age 0-17 years in households not living with a biological parent and percentage of children who have one or both biological parents dead. It also shows percentage of children living with neither parent, mother only, and father only.

The SHHS2 findings indicate that 76.2 per cent of children aged 0-17 years in Sudan live with both parents. About 4.1 per cent of children were not living with a biological parent. About 17.8 per cent of live with only their mother while about 1.9 per cent live with only their father. The proportion of children who did not live with a biological parent was slightly higher in the case of female children (5.0 per cent) than that in the case of male children (3.3 per cent). The proportion of children who did not live with a biological parent was slightly higher in rural areas (4.3 per cent) than that in urban areas (3.7 per cent). The proportion of children who did not live with a biological parent was highest (10.8 per cent) among those in the age group 15-17 years and lowest (1.2 per cent) among those in the age group 0-4 years.

The percentage of children who did not live with a biological parent ranged from 2.3 per cent in Khartoum State to 6.6 per cent in South Darfur State.

Prevalence of orphans

Nationwide, the prevalence of orphans (percentage of children under age 18 who have one or both of their parents dead) was 5.7 per cent. There was only a marginal difference in the percentage of children who had one or both of their parents dead between female children (5.7 per cent) and male children (5.6 per cent). The proportion of children who had one or both of their parents dead was marginally higher in urban areas (6.5 per cent) than that in rural areas (5.3 per cent). The proportion of children who did not live with a biological parent was highest among those aged 15-17 years (12.2 per cent) and lowest among those aged 0-4 years (1.8 per cent). The prevalence of orphans ranged from 3.2 per cent in River Nile State to 7.4 per cent in South Darfur State.

Figure 10.13: Prevalence of orphans

[1] SHHS indicator 7.12; [2] SHHS indicator 7.13

School attendance of orphans and non-orphans

One of the measures developed for the assessment of the status of orphaned children relative to their peers looks at the school attendance of children age 10-14 years who have lost both parents (double orphans) versus children whose parents are alive (and who live with at least one of these parents). If children whose parents have died do not have the same access to school as their peers, then families and schools are not ensuring that these children's rights are being met.

Table 10.12 provides information relating to school attendance of orphans and non-orphans. It indicates school attendance of children age 10-14 years by orphanhood. In Sudan, the percentage of children aged 10-14 years whose mother and father have died (double orphans) was 0.3 per cent while the percentage of children of whom both parents were alive and the child was living with at least one parent (non-orphans) at the time of SHHS2 was 87.5 per cent. Among the double orphans, only 78.8 per cent were attending school compared to 81.8 per cent among children aged 10-14 years who have not lost a parent and who live with at least one parent (non-orphans). This would suggest that double orphans are disadvantaged compared to the non-orphaned children in terms of school attendance. The orphans to non-orphans school attendance ratio was 0.96.

Table 10.12: School attendance of orphans and non-orphans
School attendance of children age 10-14 years by orphanhood, Sudan, 2010

	Percentage of children whose mother and father have died	Percentage of children of whom both parents are alive and child is living with at least one parent (non-orphans)	Number of children age 10-14 years	Percentage of children who are orphans and are attending	Total number of orphan children age 10-14 years	Percentage of children who are non-orphans and are attending	Total number of non-orphan children age 10-14 years	Orphans to non-orphans school attendance ratio

[1] SHHS indicator 7.14; MDG indicator 7.15

The proportion of children age 10-14 years whose mother and father have died (double orphans) was slightly higher for male children (0.4 per cent) than that for female children (0.2 per cent). The proportion of children age 10-14 years who were orphans and were attending school was higher among male children (85.0 per cent) than that among female children (69.3 per cent). The proportion of male children age 10-14 years who were non-orphans and were attending school was also higher (85.0 per cent) than that for female children (78.5 per cent). The orphan to non-orphan school attendance rate was also higher (1.0) for male children than that for female children (0.88).

There was only a marginal difference in the proportion of children age 10-14 years whose mother and father have died (double orphans) between children in urban areas (0.5 per cent) and children in rural areas (0.2 children). The proportion of children in rural areas age 10-14 years who were orphans and were attending school was higher among children in urban areas (94.8 per cent) than that among children in rural areas (65.4 per cent). The proportion of children age 10-14 years who were non-orphans and were attending school was also higher among children in urban areas (92.0 per cent) than that among children in rural areas (77.6 per cent). The orphan to non-orphan school attendance rate was also higher (1.03) for children in urban areas than that for children in rural areas (0.96).

XI. HIV/AIDS, Knowledge and Attitude

The strong linkage between spread of HIV/AIDS and behavioural patterns of people make it essential, for the purpose of halting and reversing the incidence of HIV, to have strong emphasis on behavioural change. Appropriate knowledge about the disease is seen as an indispensable starting point for changing behaviours. In order to avoid risky behaviours, people need to know about routes of HIV transmission and consequently the methods of prevention. They also need to be able to reject the common misconceptions about the illness. Misconceptions about HIV are common and can confuse young people and hinder prevention efforts.

One of the most important prerequisites for reducing the rate of HIV infection, therefore, is accurate knowledge of how HIV is transmitted and strategies for preventing transmission. Correct information is the first step toward raising awareness and giving young people the tools to protect oneself from HIV infection. The UN General Assembly Special Session on HIV/AIDS (UNGASS) called on governments to undertake measures to improve the knowledge and skills of young people to protect themselves from HIV. The indicators to measure this goal as well as the MDG of reducing HIV infections by half include improving the level of knowledge of HIV and its prevention, and changing behaviours to prevent further spread of the disease. Under the SHHS2, the HIV module was administered to women and men age 15-49 years.

Knowledge about HIV Transmission and Misconception about HIV/AIDS

One indicator which is both an MDG and UNGASS indicator is the percentage of young women who have comprehensive and correct knowledge of HIV prevention and transmission. In SHHS all women and men who have heard of AIDS were asked whether they knew of the two main ways of HIV transmission, i.e. having only one faithful uninfected partner and using a condom every time. Table 11.1 provides information relating to the percentage of women age 15-49 years who have heard of AIDS, percentage of women who have knowledge about HIV transmission, percentage of women age 15-49 years who know the main ways of preventing HIV transmission, percentage of women who know that a healthy looking person can have the AIDS virus, percentage of women who reject common misconceptions, and percentage of women who have comprehensive knowledge about HIV transmission.

Women age 15-49 years who have heard about AIDS: The SHHS2 data indicated that overall, more than three-fourths (76.4 per cent) of women age 15-49 years have heard of AIDS. The percentage of women who have heard of AIDS was highest among women in the age group 25-29 years (78.1 per cent) and lowest among women in the age group 40-49 years (75.6 per cent). The percentage of women who have heard of AIDS was higher among women in urban areas (90.8 per cent) than among women in rural areas (69.2 per cent). The percentage of women who have heard of AIDS was higher among women who were never married (82.1 per cent) than that among women who were ever married (74.1 per cent). The percentage of women who have heard of AIDS was relatively lower among women age 15-49 years with no formal education (55.6 per cent) than that among women with primary education (83.9 per cent) and among women with secondary or higher level of education (97.8 per cent). The percentage of women who have heard of AIDS was only 56.0 among women from households in the poorest quintile compared to 96.0 for

Table 11.1: Knowledge about HIV transmission, misconceptions about HIV/AIDS, and comprehensive knowledge about HIV transmission
Percentage of women age 15-49 years who know the main ways of preventing HIV transmission, percentage who know that a healthy looking person can have the AIDS virus, percentage who reject common misconceptions, and percentage who have comprehensive knowledge about HIV transmission Sudan, 2010

	Percentage who have heard of AIDS	Percentage who know transmission can be prevented by:			Percentage who know that a healthy looking person can have the AIDS virus	Percentage who know that HIV cannot be transmitted by:			Percentage who reject the two most common misconceptions and know that a healthy looking person can have the AIDS virus	Percentage with comprehensive knowledge [1]	Number of women

women belonging to households in the richest quintile. The proportion of women age 15-49 years who have heard of AIDS ranged from 52.6 per cent in Red Sea State to 91.8 per cent in Khartoum State.

Knowledge of the ways of preventing HIV transmission (women age 15-49 years)

The SHHS2 findings indicated that 62.0 per cent of women age 15-49 years knew of having one faithful uninfected sex partner and 17.2 per cent of them knew of using a condom every time during sexual intercourse as main ways of preventing HIV transmission. However, the proportion of women who knew of both the main ways of preventing HIV transmission was only 15.8 per cent. The percentage of women who knew that one could prevent HIV transmission by having one faithful uninfected sex partner was highest among women in the age group 25-29 years (63.6 per cent) and lowest among women in the age group 40-49 years (60.2 per cent). The proportion of women who knew that one could prevent HIV transmission by using a condom every time was highest among women in the age group 25-29 years (18.4 per cent) and lowest among women in the age group 40-49 years (15.8 per cent), while the proportion of women who knew both the ways of preventing HIV transmission was also highest among women in the age group 25-29 years (17.3 per cent) and lowest among women in the age group 40-49 years (14.5 per cent).

The proportion of women age 15-49 years who knew the main ways of preventing HIV transmission was higher among women in urban areas than among women in rural areas. The proportion of women aged 15-49 years who knew that one could prevent HIV transmission by having one faithful uninfected sex partner was 78.1 per cent among women in urban areas compared to 53.7 per cent among women in rural areas. The proportion of women aged 15-49 years who knew that one could prevent HIV transmission by using a condom every time during sexual intercourse was 25.3 per cent among women in urban areas compared to 13.0 per cent among women in rural areas while the proportion of women aged 15-49 years who knew both the ways of preventing HIV transmission was 23.6 per cent among women in urban areas compared to 11.8 per cent among women in rural areas.

The proportion of women age 15-49 years who knew the main ways of preventing HIV transmission was higher among women who were never married than among women ever married. The proportion of women who knew that one could prevent HIV transmission by having one faithful uninfected sex partner was 66.8 per cent among women who were never married compared to 59.8 per cent among women ever married. The proportion of women age 15-49 years who knew that one could prevent HIV transmission by using a condom every time was 19.5 per cent among women who were never married compared to 16.1 per cent among women ever married while the proportion of women aged 15-49 years who knew both the ways of preventing HIV transmission was 17.7 per cent among women who were never married compared to 15.0 per cent among women ever married.

The proportion of women who knew the main ways of preventing HIV transmission varied with women's educational level and household wealth. For instance, only 39.1 per cent of women with no formal education knew that one could prevent HIV transmission by having one faithful uninfected sex partner compared to 69.2 per cent among women with primary education and 85.7 per cent among those with secondary or higher level of education. Only 7.6 per cent of women with no formal education knew that one could prevent HIV transmission by using a condom every time compared to 16.7 per cent among women with primary education and 31.3 per cent among those with secondary or higher level of education. Only 6.6 per cent of women with no formal education knew both the ways of preventing HIV transmission compared to 15.7 per cent among women with primary education and 28.9 per cent among those with secondary or higher level of education.

The proportion of women age 15-49 years who knew that one could prevent HIV transmission by having one faithful uninfected sex partner was only 40.7 among women from households in the poorest quintile compared to 83.4 among women from households in the richest quintile. Similarly, the proportion of women who knew that one could prevent HIV transmission by using a condom every time was only 7.3 per cent among women from households in the poorest quintile compared to 29.7 per cent among women from households in the richest quintile. The proportion of women who knew both ways of preventing HIV transmission was only 6.5 per cent among women from households in the poorest quintile compared to 27.7 per cent among women from households in the richest quintile.

The proportion of women aged 15-49 years who knew the main ways of preventing HIV transmission varies substantially by State of residence. The proportion of women who knew both ways of preventing HIV transmission ranged from 20.0 per cent in Northern State to 3.6 per cent in West Darfur State.

Knowledge of the fact that a healthy looking person can have the AIDS virus (women aged 15-49 years)

Overall, 36.2 per cent of women age 15-49 years knew that a healthy looking person could have the AIDS virus. The proportion of women who knew that a healthy looking person could have the AIDS virus was higher among women in urban areas (54.9 per cent) than among women in rural areas (26.5 per cent). The proportion of women who knew that a healthy looking person could have the AIDS virus was higher among women who were never married (45.1 per cent) than among women ever married (32.3 per cent). The percentage of women who knew that a healthy looking person could have the AIDS virus varied with women's educational level and level of household wealth. For instance, only 16.6 per cent of women who had no formal education knew that a healthy looking person could have the AIDS virus compared to 35.7 per cent among women with primary education and 64.1 per cent among those with secondary or higher level of education. The proportion of women who knew that a healthy looking person could have the AIDS virus was only 16.3 per cent among women from households in the poorest quintile compared to 62.6 per cent among women from households in the richest quintile. The percentage of women age 15-49 years who knew that a healthy looking person could have AIDS virus ranged from 13.8 per cent in West Darfur State to 59.8 per cent in Khartoum State.

Knowledge of common misconceptions concerning HIV transmission (women aged 15-49 years)

Table 11.1 also presents information regarding the proportion of women aged 15-49 years who reject common misconceptions concerning HIV. The indicator is based on the three most common and relevant misconceptions that HIV can be transmitted by mosquito bites, by supernatural means and by sharing food with someone with AIDS. The table provides information regarding the percentage of women who know that HIV cannot be transmitted by mosquito bites, by supernatural means and by sharing food with someone with AIDS. It also provides information relating to the percentage of women age 15-49 years who reject the two most common misconceptions and know that a healthy looking person can have the AIDS virus.

The SHHS2 data indicated that overall, 43.4 per cent of women age 15-49 years knew that HIV could not be transmitted by mosquito bite while 58.8 per cent of them knew that HIV could not be transmitted by supernatural means. About 51.4 per cent of them knew that HIV could not be transmitted by sharing food with someone with AIDS. The proportion of women age 15-49 years who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was 19.3 per cent.

The proportion of women age 15-49 years who knew that HIV could not be transmitted by mosquito bites or supernatural means or by sharing food with someone with AIDS varied among women from rural and urban areas. For instance, while the proportion of women who believed that HIV could not be transmitted by mosquito bite was only 34.6 per cent among women in rural areas, it was 60.6 per cent among women from urban areas. The proportion of women who knew that HIV could not be transmitted through supernatural means was 49.8 per cent among women in rural areas compared to 76.1 per cent among women from urban areas. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was 42.1 per cent among women in rural areas compared to 69.4 per cent among women from urban areas. The proportion of women age 15-49 years who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 12.2 per cent among women in rural areas compared to 33.1 per cent among women from urban areas.

The proportion of women age 15-49 years who know that HIV could not be transmitted by mosquito bite or by supernatural means or by sharing food with someone with AIDS also varied with the marital status of the woman. For instance, the proportion of women who believed that HIV could not be transmitted by mosquito bite was only 37.8 per cent among women ever married compared to 56.3 per cent among women who were never married. The proportion of women who knew that HIV could not be transmitted through supernatural means was 54.8 per cent among women ever married compared to 68.1 per cent among women who were never married. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was only 47.7 per cent among women ever married compared to 60.1 per cent among women who were never married. The proportion of women aged 15-49 years who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 15.7 per cent among women ever married compared to 27.6 per cent among women who were never married.

The proportion of women age 15-49 years who know that HIV could not be transmitted by mosquito bite or by supernatural means or by sharing food with someone with AIDS varied with educational level of the women. For instance, while the proportion of women who believed that HIV could not be transmitted by mosquito bite was only 18.7 per cent among those with no formal education, it was 45.4 per cent among

women with primary education and 75.6 per cent among those with secondary or higher level of education. The proportion of women who knew that HIV could not be transmitted through supernatural means was only 31.7 per cent among those with no formal education compared to 65.3 per cent among women with primary education and 88.3 per cent among those with secondary or higher level of education. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was only 26.3 per cent among those with no formal education compared to 57.2 among women with primary education and 79.5 per cent among those with secondary or higher level of education. The proportion of women age 15-49 years who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 4.3 per cent among those with no formal education compared to 16.4 per cent among women with primary education and 43.5 per cent among those with secondary or higher level of education.

The proportion of women age 15-49 years who knew that HIV could not be transmitted by mosquito bites or supernatural means or by sharing food with someone with AIDS also varied with household wealth. For instance, while the proportion of women who believed that HIV could not be transmitted by mosquito bite was only 19.4 per cent among women from households in the poorest quintile, it was 73.4 per cent among women from households in the richest quintile. The percentage of women who knew that HIV could not be transmitted through supernatural means was only 36.0 per cent among those from households in the poorest quintile compared to 84.1 among women from households in the richest quintile. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was only 26.6 per cent among those from households in the poorest quintile compared to 75.6 per cent among women from households in the richest quintile. The proportion of women who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 4.8 per cent among those from households in the poorest quintile compared to 41.5 per cent among women from households in the richest quintile.

The proportion of women aged 15-49 years who believed that HIV could not be transmitted by mosquito bites ranged from 16.0 per cent in West Darfur State to 66.6 per cent in Khartoum State.

The proportion of women aged 15-49 years who believed that HIV could not be transmitted through supernatural means ranged from 29.5 in West Darfur State to 77.3 in Khartoum State.

The proportion of women aged 15-49 years who believed that HIV could not be transmitted by sharing food with someone with AIDS ranged from 25.6 in West Darfur State to 69.6 in Khartoum State.

The proportion of women aged 15-49 years who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus ranged from 4.1 per cent in West Darfur State to 38.2 per cent in Khartoum State.

Comprehensive knowledge (among women age 15-49 years) about HIV prevention and transmission

Table 11.1 also presents the proportion of women age 15-49 years with comprehensive knowledge about HIV prevention and transmission. Women who have comprehensive knowledge about HIV prevention and transmission include those who know of the two ways of HIV prevention (having only one faithful uninfected partner and using a condom every time), who know that a healthy looking person can have the AIDS virus, and who reject the two most common misconceptions. Comprehensive knowledge of HIV prevention is still very low. Overall, only 5.8 per cent of women were found to have comprehensive knowledge of HIV prevention, which was higher among women in urban areas (11.4 per cent) than among women in rural areas (3.0 per cent). The proportion of women who had comprehensive knowledge about HIV prevention was highest among women in the age group 30-39 years (7.2 per cent) and lowest among women in the age group 40-49 years (4.4 per cent).

The proportion of women age 15-49 years who had comprehensive knowledge about HIV prevention was higher among women who were never married (7.4 per cent) than that among women ever married (5.2 per cent). The proportion of women who had comprehensive knowledge about HIV prevention varied with woman's educational level and household wealth. For instance, only 0.9 per cent of women who had no formal education had comprehensive knowledge about HIV prevention compared to 4.2 per cent among women with primary education and 14.7 per cent among those with secondary or higher level of education. The proportion of women who had comprehensive knowledge about HIV prevention and transmission was only 0.8 per cent among women from households in the poorest quintile compared to 13.5 per cent among women from households in the richest quintile. The proportion of women age 15-49 years who had

comprehensive knowledge about HIV prevention ranged from 1.0 per cent in West Darfur State to 10.8 per cent in Khartoum State.

Knowledge about HIV prevention among women age 15-24 years

Young women age 15-24 years who have heard of AIDS: Table 11.2 presents information relating to the awareness of AIDS among young women age 15-24 years (i.e. proportion of women age 15-24 years who have heard of AIDS). Overall, more than three-fourths (76.4 per cent) of women aged 15-24 years have heard of AIDS. The percentage of young women who have heard of AIDS was higher among women in the age group 20-24 years (78.5 per cent) than that among women in the age group 15-19 years (74.5 per cent). The percentage of young women who have heard of AIDS was higher among women in urban areas (90.7 per cent) than that among women in rural areas (68.8 per cent). The percentage of young women who have heard of AIDS was higher among women who were never married (80.9 per cent) than that among women who were ever married (70.0 per cent). The percentage of young women who have heard of AIDS was found to be low among women with no formal education. Only 46.2 per cent of those with no formal education have heard of AIDS compared to 78.5 per cent among women with primary education and 97.1 per cent among women with secondary or higher level of education. The awareness of AIDS was also particularly low among women from households in the poorest quintile. The proportion of women who have heard of AIDS was only 53.2 per cent among women from households in the poorest quintile compared to 95.4 per cent among women belonging to households in the richest quintile. The awareness of AIDS among women age 15-49 years also varies substantially by State of residence. The proportion of women age 15-49 years who have heard of AIDS ranged from 48.4 per cent in West Darfur State to 91.4 per cent in White Nile State.

Knowledge (among women aged 15-24 years) of the main ways of preventing HIV transmission

The SHHS2 findings indicated that 61.8 per cent of women age 15-24 years knew of having one faithful uninfected sex partner and 16.8 per cent knew of using a condom every time as main ways of preventing HIV transmission. However, the proportion of women who knew of both the main ways of preventing HIV transmission was only 15.4 per cent

among women in urban areas compared to 54.0 per cent among women in rural areas. The proportion of women who knew that one could prevent HIV transmission by using a condom every time was 23.2 per cent among women in urban areas compared to 13.4 per cent among women in rural areas. The proportion of women who knew both the ways of preventing HIV transmission was 21.4 per cent among women in urban areas compared to 12.2 per cent among women in rural areas.

The proportion of women aged 15-24 years who knew the main ways of preventing HIV transmission was higher among women who were never married than among women ever married. The proportion of women who knew that one could prevent HIV transmission by having one faithful uninfected sex partner was 65.7 per cent among women who were never married compared to 56.1 per cent among women ever married. The proportion of women who knew that one could prevent HIV transmission by using a condom every time was 18.1 per cent among women who were never married compared to 14.9 per cent among women ever married. The proportion of women who knew both the ways of preventing HIV transmission was 16.4 per cent among women who were never married compared to 14.0 per cent among women ever married.

The proportion of women age 15-24 years who knew the main ways of preventing HIV transmission varied with women's level of education and household wealth. For instance, only 31.5 per cent of women with no formal education knew that one could prevent HIV transmission by having one faithful uninfected sex partner compared to 62.8 per cent among women with primary education and 83.5 per cent among those with secondary or higher level of education. Only 6.6 per cent of women with no formal education knew that one could prevent HIV transmission by using a condom every time compared to 14.1 per cent among women with primary education and 27.0 per cent among those with secondary or higher level of education while only 5.8 per cent of women with no formal education knew both the ways of preventing HIV transmission compared to 13.2 per cent among women with primary education and 24.8 per cent among those with secondary or higher level of education.

The proportion of women age 15-24 years who knew that one could prevent HIV transmission by having one faithful uninfected sex partner was only 39.4 among women from households in the poorest quintile compared to 81.7 among women from households in the richest quintile. Similarly, the proportion of women who knew that one could prevent HIV transmission by using a condom every time was only 8.3 among women from households in the poorest quintile compared to 25.3 among women from households in the richest quintile. The proportion of women who knew both ways of preventing HIV transmission was only 7.1 among households in the poorest quintile compared to 23.7 among women from households in the richest quintile.

The proportion of women age 15-24 years who knew the main ways of preventing HIV transmission varies substantially by State of residence. The percentages of women who knew both ways of preventing HIV transmission ranged from 3.7 in West Darfur State to 20.6 in Khartoum State.

Knowledge (among women aged 15-24 years) of the fact that a healthy looking person can have the AIDS virus

Table 11.2 also presents information regarding the proportion of women age 15-24 years who know that a healthy looking person can have the AIDS virus. Overall, 36.2 per cent of women age 15-24 years knew that a healthy looking person can have the AIDS virus. The proportion of women who knew that a healthy looking person could have the AIDS virus was higher among women in urban areas (54.8 per cent) than that among women in rural areas (26.2 per cent).

The proportion of women age 15-24 years who knew that a healthy looking person could have the AIDS virus was higher among women who were never married (42.8 per cent) than among women ever married (26.8 per cent). The proportion of women who knew that a healthy looking person could have the AIDS virus varied with women's level of education and household wealth. For instance, only 12.8 per cent of women who had no formal education knew that a healthy looking person could have the AIDS virus compared to 30.7 per cent among women with primary education and 58.9 per cent among those with secondary or higher level of education. The proportion of women who knew that a healthy looking person could have the AIDS virus was only 17.7 among women from households in the poorest quintile compared to 60.1 among women from households in the richest quintile.

The proportion of women age 15-24 years who knew that a healthy looking person could have AIDS virus ranged from 11.3 per cent in West Darfur State to 56.8 per cent in Khartoum State.

Knowledge (among women aged 15-24 years) of common misconceptions concerning HIV transmission

Table 11.2 also presents information regarding the proportion of women aged 15-24 years who reject common misconceptions concerning HIV. It also provides information relating to the percentage of women aged 15-24 years who reject the two most common misconceptions and know that a healthy looking person can have the AIDS virus.

Overall, 46.2 per cent of women age 15-24 years knew that HIV could not be transmitted by mosquito bites while 60.5 per cent of them knew that HIV could not be transmitted through supernatural means. About 53.1 per cent of them knew that HIV could not be transmitted by sharing food with someone with AIDS. The proportion of women aged 15-24 years who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was 19.9 per cent.

The proportion of women age 15-24 years who know that HIV could not be transmitted by mosquito bite or by supernatural means or by sharing food with someone with AIDS varied among women from rural and urban areas. For instance, while the proportion of women who believed that HIV could not be transmitted by mosquito bite was only 37.3 per cent among women in rural areas, it was 63.0 per cent among women from urban areas. The proportion of women who knew that HIV could not be transmitted through supernatural means was 51.4 per cent among those in rural areas compared to 77.6 per cent among women from urban areas. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was 44.1 per cent among women in rural areas compared to 70.1 per cent among women from urban areas. The proportion of women who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 12.5 per cent among women in rural areas compared to 33.9 per cent among women from urban areas.

The proportion of women age 15-24 years who knew that HIV could not be transmitted by mosquito bite or by supernatural means or by sharing food with someone with AIDS also varied with the marital status of the woman. For instance, the proportion of women who believed that HIV could not be transmitted by mosquito bite was only 33.5 per cent among women ever married compared to 55.2 per cent among women who were never married. The proportion of women who knew that HIV could not be transmitted through supernatural means was 51.4 per cent among women ever married compared to 67.0 per cent among women who were never married/in union. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was only 44.0 per cent among women ever married compared to 59.6 per cent among women who were never married. The proportion of women who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 10.9 per cent among women ever married compared to 26.3 per cent among women who were never married.

The proportion of women age 15-24 years who know that HIV could not be transmitted by mosquito bite or by supernatural means or by sharing food with someone with AIDS also varied with the level of education of the woman. For instance, while the proportion of women who believed that HIV could not be transmitted by mosquito bite was only 15.6 per cent among those with no formal education, it was 40.7 per cent among women with primary education and 74.0 per cent among those with secondary or higher level of education. The proportion of women who knew that HIV could not be transmitted through supernatural means was only 24.8 per cent among those with no formal education compared to 59.1 per cent among women with primary education and 87.8 per cent among those with secondary or higher level of education. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was only 22.0 per cent among women with no formal education compared to 50.4 among women with primary education and 78.7 per cent among women with secondary or higher level of education. The proportion of women who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 2.6 per cent among those with no formal education compared to 12.5 per cent among women with primary education and 40.0 per cent among women with secondary or higher level of education.

The proportion of women aged 20-24 years who knew that HIV could not be transmitted by mosquito bite or by supernatural means or by sharing food with someone with AIDS also varied with the household wealth. For instance, while the proportion of women who believed that HIV could not be transmitted by mosquito bites was only 21.4 per cent among women from households in the poorest quintile, it was 75.2 per cent among women from households in the richest quintile. The proportion of women who knew that HIV could not be transmitted through supernatural means was only 35.7 per cent among women from households in the poorest quintile compared to 84.9 among women from households in the richest quintile. The proportion of women who knew that HIV could not be transmitted by sharing food with someone with AIDS was only

29.1 per cent among those from households in the poorest quintile compared to 74.0 per cent among women from households in the richest quintile. The proportion of women who rejected the two most common misconceptions and knew that a healthy looking person could have the AIDS virus was only 5.8 per cent among women from households in the poorest quintile compared to 41.4 among women from households in the richest quintile.

The knowledge (among women age 15-24 years) about HIV transmission and misconceptions about HIV/AIDS varies substantially by State of residence. The proportion of women who believed that HIV could not be transmitted by mosquito bites ranged from 13.6 per cent in West Darfur State to 70.8 per cent in Khartoum State. The proportion of women who believed that HIV could not be transmitted through supernatural means ranged from 26.7 in West Darfur State to 78.8 in Khartoum State. The proportion of women who believed that HIV could not be transmitted by sharing food with someone with AIDS ranged from 25.0 in West Darfur State to 68.2 in Khartoum State. The proportion of women who rejected the two most common misconceptions and knew that a healthy looking person could have AIDS virus ranged from 4.1 per cent in West Darfur State to 38.2 per cent in Khartoum State.

Comprehensive knowledge about HIV prevention among women aged 15-24 years

Table 11.2 also presents information relating to the proportion of women age 15-24 years with comprehensive knowledge about HIV prevention and transmission. Overall, only 5.3 per cent of women age 15-24 years had comprehensive knowledge about HIV prevention, which was higher among women in urban areas (9.9 per cent) than among women in rural areas (2.9 per cent). The proportion of women who had comprehensive knowledge about HIV prevention and transmission was higher among women in the age group 20-24 years (6.5 per cent) than that among women in the age group 15-19 years (4.3 per cent).

The proportion of women age 15-24 years who had comprehensive knowledge about HIV prevention and transmission was higher among women who were never married (6.4 per cent) than among women ever married (3.8 per cent). The proportion of women who had comprehensive knowledge about HIV prevention and transmission varied with woman's level of education and household wealth. For instance, only 0.5 per cent of women who had no formal education had comprehensive knowledge about HIV prevention and transmission compared to 2.8 per cent among women with primary education and 11.5 per cent among those with secondary or higher level of education. The proportion of women who had comprehensive knowledge about HIV prevention and transmission was only 0.8 per cent among women from households in the poorest quintile compared to 10.9 per cent among women from households in the richest quintile. The proportion of women age 15-24 years with comprehensive knowledge about HIV transmission and prevention ranged between 1.0 per cent in West Darfur State and 9.1 in Gadarif State.

Figure 11.2: Comprehensive knowledge about HIV prevention
Percentage of women age 15-24 years with comprehensive knowledge about HIV prevention, Sudan, 2010

Knowledge of mother-to-child transmission of HIV

Knowledge of mother-to-child transmission of HIV is also an important first step for women to seek HIV testing when they are pregnant to avoid infection in the baby. Women should know that HIV can be transmitted during pregnancy, delivery, and through breastfeeding. The level of knowledge among women age 15-49 years concerning mother-to-child transmission is presented in Table 11.5.

Table 11.5: Knowledge of mother-to-child HIV transmission
Percentage of women age 15-49 years who correctly identify means of HIV transmission from mother to child, Sudan, 2010

State of residence	Percentage who know HIV can be transmitted from mother to	Percent who know HIV can be transmitted:				Does not know any of the specific means	Number of women
		During pregnancy	During delivery	By breastfeeding	All three means [1]		
Northern	72.8	64.3	49.3	55.1	37.2	15.2	351
River Nile	61.3	54.8	49.4	38.9	31.4	17.9	637
Red Sea	40.4	33.8	28.3	23.1	15.7	12.2	477
Kassala	44.3	39.7	36.4	34.1	27.0	19.0	1004
Gadarif	58.1	50.1	46.9	38.5	29.7	16.1	773
Khartoum	76.7	70.5	62.1	50.6	42.6	15.1	3005
Gezira	67.6	52.6	50.6	43.8	30.5	16.0	2791
White Nile	76.2	64.5	56.4	54.6	38.6	14.7	906
Sinnar	53.9	45.7	40.1	41.5	30.1	14.5	675
Blue Nile	40.1	33.1	32.4	31.0	22.9	12.8	566
North Kordofan	57.4	51.1	45.7	47.8	37.8	15.0	1765
South Kordofan	52.4	43.9	40.7	40.4	29.4	22.1	700

group 20-24 years (54.8 per cent) and lowest among women in the age group 15-19 years (50.6 per cent). The proportion of women who knew that HIV could be transmitted from mother to child during delivery was highest among women in the age group 20-24 years (48.4 per cent) and lowest among women in the age group 15-19 years (45.9 per cent). The proportion of women who knew that HIV could be transmitted from mother to child by breast feeding was highest among women in the age group 20-24 years (45.3 per cent) and lowest among women in the age group 40-49 years (39.8 per cent). The proportion of women who knew all three ways of HIV transmission from mother to child was highest among women in the age group 20-24 years (34.1 per cent) and lowest among women in the age group 30-39 years (31.5 per cent). The proportion of women who did not know any of the specific means to prevent HIV transmission from mother-to-child was highest among women in the age group 25-29 years (17.6 per cent) and lowest among women in the age group 15-19 years (14.6 per cent).

The proportion of women aged 15-49 years who know that AIDS can be transmitted from mother to child seems to vary between women in rural and urban areas, being 51.7 per cent among women in rural areas and 77.0 per cent among those from urban areas. The proportion of women who knew that HIV could be transmitted from mother to child during pregnancy was only 42.8 per cent among women from rural areas compared to 69.0 per cent among those from urban areas; the proportion of women who knew that HIV could be transmitted from mother to child during delivery was only 39.5 per cent among women from rural areas compared to 61.4 among those from urban areas; the proportion of women who knew that HIV could be transmitted from mother to child by breast feeding was only 38.7 per cent among women from the rural areas compared to 51.5 per cent among those from urban areas.

Similarly, the proportion of women who knew all three ways of HIV transmission from mother to child also varied between women in rural and urban areas, the proportion being 28.1 per cent among women from rural areas and 41.4 per cent among those from urban areas. The proportion of women who did not know any specific way to prevent HIV transmission from mother-to-child was 17.5 per cent among women from rural areas compared to 13.8 per cent among those from urban areas.

The proportion of women aged 15-49 years who know that AIDS can be transmitted from mother to child seems to vary among women ever married and women never married, the proportion being 56.6 per cent among women ever married and 68.8 per cent among women never married. The proportion of women who knew that HIV could be transmitted from mother to child during pregnancy was only 48.5 per cent among women ever married compared to 59.0 per cent among those women never married; the proportion of women who knew that HIV could be transmitted from mother to child during delivery was only 44.1 per cent among women ever married compared to 53.4 per cent among those women never married; the proportion of women who knew that HIV could be transmitted from mother to child by breast feeding was only 40.8 among women ever married compared to 48.3 per cent among those women never married. Similarly, the proportion of women who knew all three ways of HIV transmission from mother to child also varied between women ever married and women never married, the percentages being 31.0 per cent among women ever married and 36.5 per cent among those never married. The percentage of women who did not know any specific way to prevent HIV transmission from mother-to-child was 17.5 per cent among women ever married compared to 13.3 per cent among those women never married.

The proportion of women aged 15-49 years who knew that HIV can be transmitted from mother to child appears to increase with the woman's education level, the proportion being 36.4 per cent among women with no formal education compared to 66.5 per cent among those with primary education and 86.6 per cent among women with secondary or higher level of education. The proportion of women who knew that HIV could be transmitted from mother to child during pregnancy was only 31.0 per cent among women with no formal education compared to 56.0 per cent among women with primary education and 75.8 per cent among women with secondary or higher level of education. The proportion of women who knew that HIV could be transmitted from mother to child during delivery was only 28.0 per cent among women with no formal education compared to 51.4 per cent among those with primary education and 68.5 per cent among women with secondary or higher level of education. Similarly, the proportion of women who knew all three ways of HIV transmission from mother to child was only 22.1 per cent among women with no formal education compared to 36.4 per cent among women with primary education and 43.4 per cent among women with secondary or higher level of education. The proportion of women who did not know any specific way to prevent HIV transmission from mother-to-child appears to decrease with higher level of education among women, the proportion being 19.2 per cent among women with no formal education compared to 17.4 per cent among those with primary education and 11.3 per cent among women with secondary or higher level of education.

The proportion of women aged 15-49 years who know that AIDS can be transmitted from mother to child also seems to increase with household wealth, the proportion being 37.5 per cent among women from households in the poorest quintile and 83.9 per cent among those from households in the richest quintile. The proportion of women who knew that HIV could be transmitted from mother to child during pregnancy was only 31.5 per cent among women from households in the poorest quintile compared to 74.8 per cent among those from households in the richest quintile; the proportion of women who knew that HIV could be transmitted from mother to child during delivery was only 28.0 among women from households in the poorest quintile compared to 65.7 per cent among those from households in the richest quintile; the proportion of women who knew that HIV could be transmitted from mother to child by breast feeding was only 30.9 per cent among women from households in the poorest quintile compared to 52.8 per cent among those from households in the richest quintile. Similarly, the proportion of women who knew all three ways of HIV transmission from mother to child also increases with the increasing level of household wealth, the proportion being 22.0 per cent among women from households in the poorest quintile to 41.3 per cent among those from households in the richest quintile. The proportion of women who did not know any specific way to prevent HIV transmission from mother-to-child appears to decrease with higher level of household wealth, the percentage being 18.5 per cent among women from households in the poorest quintile to 12.1 per cent among those from households in the richest quintile.

The proportion of women age 15-49 years who know that AIDS could be transmitted from mother to child varies substantially by State of residence, ranging from 39.1 per cent in West Darfur to 76.7 per cent in Khartoum State. The proportion of women who knew all three ways of HIV transmission from mother-to-child ranged from 15.7 per cent in Red Sea State to 42.6 per cent in Khartoum State. The proportion of women who did not know any of the specific means to prevent HIV transmission from mother-to-child ranged from 12.2 per cent in Red Sea State to 22.1 per cent in South Kordofan State.

women who expressed accepting attitudes on all four indicators was only 2.4 per cent among women with no formal education compared to 7.2 per cent among those with primary education and 13.8 per cent among women with secondary or higher level of education. The proportion of women who expressed accepting attitudes on all four indicators was 2.6 per cent among women from households in the poorest quintile compared to 10.8 among those from households in the richest quintile.

The proportion of women age 15-49 years who expressed accepting attitudes on all four indicators ranged from 3.7 per cent in West Darfur to 12.8 per cent in Red Sea State.

Knowledge of a Place for HIV Testing

Another important indicator is the knowledge of where to be tested for HIV and use of such services. In order to protect themselves and to prevent infecting others, it is important for individuals to know their HIV status. Knowledge of one's status is also a critical factor in the decision to seek treatment. Questions related to knowledge among women of a facility for HIV testing and whether they have ever been tested is presented in Table 11.9.

Overall, 14.4 per cent of women age 15-49 years knew of a place for HIV testing though only 2.5 per cent have actually been tested, 0.9 per cent have been tested in the last 12 months preceding SHHS2 and 0.5 per cent has been tested and have been told the result.

The percentage of women age 15-49 years who knew a place to get tested for HIV was higher among women in urban areas (26.1 per cent) than among those in rural areas (8.4 per cent). The percentage of women age 15-49 years who knew a place to get tested for HIV was highest among women in the age group 30-34 years (17.4 per cent) and lowest among women in the age group 15-19 years (11.1 per cent). The percentage of women who knew a place for HIV testing was slightly higher among never married women (15.1 per cent) than among ever married women (14.1 per cent).

The proportion of women age 15-49 years who knew a place for HIV testing appears to increase with the increasing level of household wealth. The proportion of women who knew a place to get tested was only 3.9 per cent among women from households in the poorest quintile compared to 29.1 per cent among those from the households in the richest quintile.

Figure 11.9: Knowledge of a place for HIV testing
Percentage of women age 15-49 years who state that they know a place to be tested for HIV, Sudan, 2010

index quintile, 8.5 per cent for those from households in the fourth wealth index quintile, 9.8 per cent for those from households in the poorest quintile and 13.0 per cent for respondents from households in the richest quintile.

The percentage of respondents with a chronic disease ranged from 4.0 per cent in Red Sea State to 11.7 per cent in Khartoum State.

Major Chronic Diseases Among People

Tables 12.4a to Table 12.4d indicate the percentage of children and adults with specific chronic disease. Figure 12.4 indicates the percent distribution of respondents with chronic disease according to diseases. The SHHS2 data indicates that the major chronic diseases that are prevalent among people of Sudan and the percent distribution of respondents according to diseases are as follows: Hypertension (24.3 per cent), Diabetes (14.5 per cent), Asthma (8.1 per cent), Hypothyroidism (6.6 per cent), Glaucoma (6.3 per cent), Cataract (4.7 per cent), Mental health-related problems (3.0 per cent), Heart disease (2.7 per cent), Rheumatic heart disease (2.7 per cent), Renal failure (2.4 per cent), TB (1.5 per cent), Epilepsy (1.3 per cent), cancer (0.3 per cent), Leprosy (0.2 per cent) and other diseases (30.6 per cent).

People with epilepsy: The SHHS2 data indicated that approximately 1.3 per cent of the respondents with chronic disease were affected by epilepsy. The percentage with epilepsy was marginally higher among those living in rural areas (1.6 per cent) than that among those living in urban areas (1.0 per cent). There was no noticeable difference in the percentage with epilepsy between male respondents (1.3 per cent) and female respondents (1.4 per cent). The percentage with epilepsy appears to decrease with the age of the respondent. The percentage with epilepsy was highest at 5.8 per cent among children in the age group 10-14 years compared to 3.1 per cent among respondents in the age group 15-34 years, 0.7 per cent among those in the age group 35-64 years and 0.4 per cent among those over age 65 years. The percentage with epilepsy shows a declining trend with increase in household wealth. The percentage with epilepsy decreased from 2.8 per cent in the case of those from households in the poorest quintile to 1.5 per cent for those from households in the second wealth index quintile, to 1.1 per cent for those from households in the middle wealth index quintile, to 1.1 per cent for those from households in the fourth wealth index quintile and to 0.5 per cent for respondents from households in the richest quintile. The percentage with epilepsy ranged from 0.4 per cent in Gezira and White Nile States to 3.6 per cent in North Darfur State.

People with asthma: The SHHS2 data also indicated that approximately 8.1 per cent of the respondents with chronic disease were affected by asthma. There was no noticeable difference in the percentage with asthma among those living in urban areas (8.0 per cent) than that among those living in rural areas (8.2 per cent). The percentage of respondents with asthma was higher for male respondents (10.2 per cent) than that for female respondents (6.5 per cent). The percentage with asthma appears to decrease with the age of the respondent. The percentage of respondents with asthma was highest at 17.6 per cent among children in the age group 10-14 years compared to 12.2 per cent among respondents in the age group 15-34 years, 7.0 per cent among those in the age group 35-64 years and 5.1 per cent among those over age 65 years. The percentage with asthma was higher among those from households in the richest quintile (8.9 per cent) than that among those from households in the poorest quintile (6.1 per cent). The percentage with asthma ranged from 3.9 per cent in South Kordofan State to 11.7 per cent in Sinnar State.

People with hypothyroidism: The SHHS2 data also indicated that approximately 6.6 per cent of the respondents with chronic disease were affected by hypothyroidism. The percentage with hypothyroidism was slightly higher among those living in urban areas (7.9 per cent) than that among those living in rural areas (5.7 per cent). The percentage with hypothyroidism was higher for female respondents (10.4 per cent) than that for male respondents (1.5 per cent). The percentage with hypothyroidism was highest at 13.9 per cent among those in the age group 15-34 years and lowest among those over age 65 years, while the percentage was 4.0 for children in the age group 10-14 years, and 6.3 among those in the age group 35-64 years. The percentage with hypothyroidism was lowest among those from households in the poorest quintile (5.7 per cent) and highest among those from households in the fourth wealth index quintile (7.7 per cent). The percentage with hypothyroidism ranged from 1.7 per cent in Blue Nile State to 11.9 per cent in White Nile State.

People with glaucoma: The SHHS2 data indicated that approximately 6.3 per cent of the respondents with chronic disease were affected by glaucoma. The percentage with glaucoma was higher among those living in rural areas (8.4 per cent) than that among those living in urban areas (2.9 per cent). The percentage with glaucoma was slightly higher for male respondents (6.9 per cent) than that for female respondents (5.8 per cent). The percentage with glaucoma was higher among those in the age group 10-14 years (13.4 per cent) and among those over age 65 years (12.3 per cent) than that among those in the age group 15-35 years,

People with mental health-related problem: The SHHS2 data also indicated that approximately 3.0 per cent of the respondents with chronic disease were affected by mental health-related problem. The percentage with mental health-related problem was slightly higher among those living in rural areas (3.5 per cent) than that among those living in urban areas (2.1 per cent). The percentage with mental health-related problem was higher for male respondents (3.7 per cent) than that for female respondents (2.4 per cent). The percentage with mental health problem was highest at 7.2 per cent among those in the age group 15-34 years compared to 4.9 per cent among children in the age group 10-14 years, 2.2 per cent among respondents in the age group 35-64 years, and 0.5 per cent among those over age 65 years. The percentage with mental health-related problem was highest among those from households in the second wealth index quintile (4.1 per cent) and lowest among those from the richest quintile (2.3 per cent). The percentage with mental health problem ranged from 1.1 per cent in South Khartoum State to 5.2 per cent in South Kordofan State.

People with TB: The SHHS2 data indicated that approximately 1.5 per cent of the respondents with chronic disease were affected by TB. There was no noticeable difference in percentage with TB among those living in urban areas (1.4 per cent) than that among those living in rural areas (1.6 per cent). The percentage with TB was slightly higher for male respondents (1.8 per cent) than that for female respondents (1.3 per cent). The percentage with TB was highest at 2.9 per cent among children in the age group 10-14 years and lowest among those over age 65 years (0.5 per cent), while the percentage was 2.1 for those in the age group 15-34 years, and 1.4 among those in the age group 35-64 years. The percentage with TB was lowest among those from households in the richest quintile (0.3 per cent) and highest among those from households in the poorest quintile (2.4 per cent). The percentage with TB ranged from zero per cent in North Darfur State to 10.5 per cent in Kassala State.

People with rheumatic heart disease: The SHHS2 data indicated that approximately 2.7 per cent of the respondents with chronic disease were affected by rheumatic heart disease. The percentage with rheumatic heart disease was higher among those living in urban areas (3.4 per cent) than that among those living in rural areas (2.2 per cent). The percentage with rheumatic heart disease was slightly higher for female respondents (2.9 per cent) than that for male respondents (2.3 per cent). The percentage with rheumatic heart disease was higher among those over age 65 years and lowest among those in the age group 15-34 years. The percentage with rheumatic heart disease was lowest among those from households in the second wealth index quintile (1.3 per cent) and highest among those from households in the fourth wealth index quintile (3.2 per cent). The percentage with rheumatic heart disease ranged from 0.3 per cent in Sinnar State to 5.3 per cent in North Khartoum State.

Table 12.4d indicates the percentage of children and adults affected by diseases such as renal failure, leprosy and other diseases.

People with renal failure and leprosy: The SHHS2 data indicated that approximately 2.4 per cent of the respondents were affected by renal failure. There was no noticeable difference in the percentage of those with renal failure between rural and urban residents and between male and female respondents. The percentage with renal failure was highest at 4.2 per cent among those in the age group 15-34 years and lowest among those over age 65 years. The percentage with percentage with renal failure was highest at 3.5 per cent among those from households in the poorest quintile and lowest at 1.3 per cent among those from households in the richest quintile. The percentage with renal failure ranged from 0.6 per cent in Kassala State to 5.6 per cent in West Darfur State. The SHHS2 data also indicated that approximately 0.2 per cent of the respondents with a chronic disease were affected by leprosy.

People with other diseases: The SHHS2 data also indicated that approximately 30.6 per cent of the respondents with chronic disease were affected by diseases other than those mentioned above. The percentage with diseases other than those mentioned above was higher among those living in rural areas (36.6 per cent) than that among those living in urban areas (21.4 per cent). There was no difference in the percentage with other diseases between male (30.6 per cent) and female respondents (30.5 per cent). The percentage with other diseases was highest at 40.2 per cent among children in the age group 40.2 per cent and lowest among those over age 65 years (24.1 per cent). The percentage with other diseases was highest among those from households in the poorest quintile (50.4 per cent) and lowest among those from households in the richest quintile (16.0 per cent). The percentage with other diseases ranges from 7.4 per cent in Northern State to 55.6 per cent in South Darfur State.

XIII. Food Security

The SHHS2 included some key indicators required to assess the situation in regard to food security of population in Sudan. The key topics covered by the SHHS2 included the food sources, dietary diversity, food consumption patterns, food security and food insecurity, and food insecurity by income sources. The key SHHS2 indicators relating to food security include the following:

- *Food consumption status:* The proportion of households with poor, borderline and acceptable/adequate food consumption score;
- *Food security status:* The proportion of food secure households;
- *Food insecurity status:* The proportion of moderately and severely food insecure households;

Food sources

Table 13.1 indicates the food sources of people in Sudan. It indicates the proportion of households which rely on own production of food items such as Sorghum, Millet, Wheat/Bread, Eggs and Milk as well as the proportion of households that rely on the market as the main source for these food items. The SHHS2 data shows that the majority of the households in Sudan rely on the market as the main food source, though the proportion of households that rely on own production of food items and those who rely on the market vary among States. The proportion of households which rely on own production of Sorghum ranged between zero per cent in Red Sea State to 40 per cent in South Kordofan State while the proportion of households which relied on the market for Sorghum ranged between 57 per cent in North Darfur State to 99 per cent in Red Sea and Khartoum States.

	Sorghum		Millet		Wheat/Bread		Eggs		Milk	
	Own production	Market purchase	Own production	Market purchase	Own production	Market purchase	Own production	Market purchase	Own production	Market purchase
Northern	11	87	6	91	13	87	19	80	21	79
River Nile	6	92	0	100	2	97	12	87	46	52

Khartoum	1	99	0	100	0	99	1	99	2	97
Gezira	21	73	5	95	1	98	15	85	20	79
White Nile	13	86	4	95	0	100	13	86	11	88
Sinnar	19	80	30	68	1	99	22	76	15	83
Blue Nile	34	65	41	57	1	98	35	63	35	64
N. Kordofan	10	88	15	84	1	99	31	67	46	53
S. Kordofan	40	59	34	65	2	98	45	55	38	61
North Darfur	22	57	29	69	0	98	36	62	32	67
West Darfur	12	67	27	70	1	93	11	85	24	73
South Darfur	20	79	32	68	1	99	35	65	36	64

The proportion of households which rely on own production of Millet ranged between zero per cent in River Nile State to 41 per cent in Blue Nile State while the proportion of households which relied on the market for Millet ranged between 57 per cent in Blue Nile State to 100 per cent in River Nile and Khartoum States.

The proportion of households which rely on own production of Wheat/Bread ranged between zero per cent in Khartoum, White Nile and North Darfur States to 13 per cent in Northern State while the proportion of households which relied on the market for procurement of Wheat/Bread ranged between 87 per cent in Northern State to 100 per cent in White Nile State.

The proportion of households which rely on own production of eggs ranged between 1 per cent in Khartoum State to 45 per cent in South Kordofan State while the proportion of households which relied on the market for eggs ranged between 63 per cent in Blue Nile State to 100 per cent in White Nile State.

The proportion of households which rely on own production of milk ranged between 2 per cent in Khartoum State to 46 per cent in River Nile and North Kordofan States while the proportion of households which relied on the market for milk ranged between 53 per cent in North Kordofan State to 97 per cent in Khartoum

State.

Food consumption Patterns and Dietary Diversity

Diets in Sudan are diverse, linked in large part to its climatic conditions and resource base. The main dietary sources for people in Sudan includes cereal, sugar, oil, milk, meat, pulses, vegetables, fruits and eggs. Though the main staples of the Sudanese diet are sorghum and millet, in certain areas, especially in pastoral areas, there is a significant amount of meat and milk consumed as well.

The SHHS2 data indicated that the urban households had a more diversified diet than rural households (Figure 13.1).

Figure 13.1: Dietary diversity by area of residence, Sudan, 2010

The SHHS2 data also indicated that the dietary diversity increases with increasing household wealth. The population living in households in the poorest quintile has a limited diet compared to households in the richest quintile (Figure 13.2).

Figure 13.2: Dietary diversity by household wealth quintiles, Sudan, 2010

Household food consumption score

Studies have shown that there is a significant correlation between diet diversity and nutrient adequacy, children's and women's anthropometry and socio-economic status (Ruel, 2003)⁹. The World Food Programme (WFP), building on this work, has created a custom dietary diversity tool intended to capture different consumption patterns, in terms of both the number and frequency of food groups consumed.

The "food consumption score" is calculated by examining the number of times certain foods (grouped into basic food groups) are eaten in the seven days preceding the survey and then weighting them by approximate nutrient density values. The food categories created and their corresponding weights are shown in Table 13.2.

Basic food group or food category	Weighting value
Cereals and tubers (sorghum, millet, maize, cassava, yams and sweet potato)	2
Pulses (beans, sesame, groundnuts)	3
Meats (beef, poultry, fish, eggs and wild game)	4
Milk/ milk products (ghii)	4
Fruits and vegetables (leaves, fruits and greens)	1
Oil and fat	0.5
Sugar	0.5

The food consumption (FC) score was calculated as follows:

FC score= (number of time cereal eaten*2) + (number of time pulses eaten*2) + (number of times meats eaten*4) + (number of time dairy eaten*4) + (number of times veggies eaten*1) + (number of times fruits eaten*1) + (number of times oil eaten*0.5) + (number of time sugar eaten*0.5)

It may be noted that the number of times any particular item was eaten was capped at 7 per week. This calculation provides each household a food consumption score, ranging up to 112. Households are then categorized into three food consumption groups according to their score: Poor food consumption, borderline food consumption, and acceptable food consumption. The thresholds are set at 21 and 35, where below 21 is considered to be poor, and more than 35 acceptable.

It may be noted that the above classification is a snapshot of the food consumption situation at the moment of the data collection and it cannot be considered representative of what households consume at other times of the year. Given livestock migration and agricultural patterns as well as the fluid security situation, the proportion of households in different food consumption groups in Sudan is likely to vary depending on both time of year and what is actually happening on the ground at the time of the survey.

Food consumption situation

Table 13.4 indicates the food consumption situation in different States of Sudan. The overall food consumption situation in Sudan is good. About 9 out of ten (89.9 per cent) of the households in Sudan have acceptable food consumption score.

⁹ Ruel M., 2003. *Operationalizing dietary diversity: a review of measurement issues and research priorities*. Journal of Nutrition 133:3922S-3926S.

State	Food consumption score		
	Households with poor food consumption score (%)	Households with borderline food consumption score (%)	Households with acceptable food consumption score (%) [1]
Northern	0.7	1.0	98.3
River Nile	0.0	0.9	99.1
Red Sea	9.4	5.7	85.0
Kassala	6.7	4.0	89.3
Gadarif	2.4	7.1	90.5
Khartoum	0.7	2.3	97.0

North Darfur	9.2	9.9	80.9
West Darfur	6.8	16.7	76.6
South Darfur	3.0	8.2	88.7
SUDAN (TOTAL)	3.5	6.6	89.9

SHHS indicator 10.1

The proportion of households that had an acceptable food consumption score ranged between 76.6 per cent in West Darfur and 99.1 per cent in River Nile State. More than 95 per cent of the households had an acceptable food consumption score in states such as River Nile (99.1 per cent), Northern (98.3 per cent), Khartoum (97.0 per cent), Gezira (96.3 per cent) and White Nile (95.1 per cent). The proportion of households with acceptable food consumption score was over 90 per cent in the States of Gadarif (90.5 per cent) and Sinnar (90.6 per cent). The percentage of households with acceptable food consumption score ranged between 85 and 90 in the States of Red Sea (85.0 per cent), South Darfur (88.7 per cent), and Kassala (89.3%) while it ranged between 80 and 85 per cent in the States of South Kordofan (83.9 per cent), North Kordofan (83.5 per cent), Blue Nile (81.8 per cent) and North Darfur (80.9 per cent). The percentage of households with acceptable food consumption score was below 80 in the State of West Darfur (76.6 per cent).

The SHHS2 data also indicated that the proportion of households that had a borderline food consumption score was 6.6 per cent. The percentage of households that had a borderline food consumption score ranged between 0.9 per cent in River Nile State and 16.7 per cent in West Darfur State. The States which had a relatively higher proportion of households with borderline consumption score included West Darfur State (16.7 per cent), Blue Nile (14.9 per cent), South Kordofan (11.4 per cent) and North Kordofan (10.5 per cent). The States which had a relatively lower proportion of households with borderline consumption score included River Nile (0.9 per cent), Northern (1.0 per cent), Khartoum (2.3 per cent) and White Nile (2.7 per cent).

The SHHS2 data indicated that the proportion of households that had a poor food consumption score was 3.5 per cent. The percentage of households that had a poor food consumption score ranged between zero per cent in River Nile State and 9.4 per cent in Red Sea State. The States which had a relatively higher proportion of households with poor consumption score included Red Sea State (9.4 per cent), North Darfur (9.2 per cent), West Darfur (6.8 per cent), Kassala (6.7 per cent) and North Kordofan (5.9 per cent). The States which had a relatively lower proportion of households with poor consumption score included River Nile (zero per cent), Northern (0.7 per cent), Khartoum (0.7 per cent), Gezira (0.9 per cent) and White Nile (0.9 per cent).

Food security situation. In this assessment, food security is an indicator based on two variables: food consumption and relative expenditure on food. In the latter indicator, less than 65 percent of total monthly expenditure on food is regarded as good and over 65 percent is poor where any changes in food prices could have a detrimental outcome.

Table 13.5 indicates the food security status of households in different States of Sudan. It indicates the percentage of households that are food secure, moderately food insecure and severely food insecure in different states of Sudan.

Food secure households: The SHHS2 data indicates that overall, the food security situation in Sudan is good. About 91.7 per cent of the households are food secure while about 5.0 per cent of the households are moderately food insecure and 3.4 per cent of the households are severely food insecure. The percentage of food secure households ranged between 79.9 per cent in West Darfur State to 99.6 per cent in River Nile State.

Figure 13.5: Food security status
Percentage of households that are food secure, Sudan, 2010

More than 95 percent of the households were food secure in States such as River Nile (99.6 per cent), Northern (98.8 per cent), Khartoum (98.0 per cent), Gezira (96.8 per cent) and White Nile (96.4 per cent). The proportion of food secure households was over 90 per cent in the States of Sinnar (93.2 per cent), Gadarif (92.5 per cent), Kassala (91.0 per cent) and South Darfur (90.8 per cent). The percentage of households that was food secure ranged between 85 and 90 in the States of Red Sea (87.6 per cent), Blue Nile (87.4 per cent), South Kordofan (85.5 per cent), and North Kordofan (85.3 per cent) while it ranged between 80 and 85 per cent in the State of North Darfur (82.9 per cent) and below 80 in the State of West Darfur (79.9 per cent).

Richest	0.1	0.6	99.3

The percentage of food secure households was higher among households whose main source of income was salaries (95.6 per cent), small business (94.1 per cent), livestock (93.7 per cent) than that for household whose main source of income were wage labour (89.8 per cent), remittances (88.9 per cent) and agriculture (82.2 per cent) and lowest among households whose main sources of income came firewood/charcoal selling.

The percentage of food secure households was higher among those in urban areas (96.7 per cent) than that in rural areas (89.5 per cent). The percentage of food secure households was higher for male-headed households (92.5 per cent) than that for female-headed households (87.6 per cent). The percentage of food secure households showed increasing trend with increasing level of education of the household head. The percentage of food secure households was lower among households which had household head with no formal education (89.1 per cent) compared to those households whose household head had primary education (94.0 per cent) and households whose household head had secondary or higher level of education (96.8 per cent).

Figure 13.7. Food security situation
Percent distribution of food secure households according to background characteristics, Sudan, 2010

The percentage of food secure households showed increasing trend with increasing level of household wealth. The percentage of food secure households increased from 84.0 per cent in the case of households in the poorest quintile to 85.1 per cent for households in the second wealth index quintile, 93.4 per cent for households in the middle wealth index quintile, 97.8 per cent for households in the fourth wealth index quintile and 99.3 per cent for households in the richest quintile.

Moderately food insecure households

The SHHS2 data indicated that the proportion of moderately food insecure households was 5.0 per cent. The percentage of moderately food insecure households ranged between 0.4 per cent in River Nile State and 13.1 per cent in West Darfur State. The States which had a relatively higher proportion of proportion of moderately food insecure households included West Darfur (7.7 per cent), North Kordofan (8.9 per cent), Blue Nile (9.1 per cent), South Kordofan (9.9 per cent) and West Darfur (13.1 per cent). The States which had a relatively lower proportion of proportion of moderately food insecure households included River Nile (0.4 per cent), Northern (0.8 per cent), Khartoum (1.6 per cent), Kassala (2.2 per cent), Gezira (2.2 per cent) and White Nile (2.8 per cent).

The proportion of moderately food insecure households was lower among those in urban areas (2.4 per cent) than among those in rural areas (6.0 per cent). The proportion of moderately food insecure households was higher for female-headed households (7.4 per cent) than that for male-headed households (4.4 per cent). The proportion of moderately food insecure households showed a decreasing trend with increasing level of education of the household head. The the proportion of moderately food insecure households was higher among households which had household head with no formal education (6.2 per cent) compared to those households whose household head had primary education (3.8 per cent) and households whose household head had secondary or higher level of education (2.2 per cent). The proportion of moderately food insecure households also showed a decreasing trend with increasing level of household wealth. The proportion of moderately food insecure households decreased from 8.6 per cent in the case of households in the poorest quintile to 4.2 per cent for households in the middle wealth index quintile, 1.6 per cent for households in the fourth wealth index quintile and to 0.6 per cent for households in the richest quintile.

The proportion of moderately food insecure households was lower among households whose main source of income was salaries (2.8 per cent), livestock (3.9 per cent) and small business (4.0 per cent) than that for household whose main source of income is wage labour (6.1 per cent), remittances (7.4 per cent) and firewood/charcoal (9.0 per cent) and highest among households whose main sources of income came agriculture (12.1 per cent).

Figure 13.8: Moderately and severely food insecure households
Percentage of moderately and severely food insecure households, Sudan, 2010

Severely food insecure households

The SHHS2 data indicated that the proportion of severely food insecure households in Sudan was 3.4 per cent. The proportion of severely food insecure households ranged between zero per cent in River Nile State and 9.4 per cent in North Darfur State.

In addition to North Darfur State, the States which had a relatively higher proportion of severely food insecure households included North Kordofan (5.8 per cent), Kassala (6.8 per cent), West Darfur (7.0 per cent)

cent), and Red Sea (9.3 per cent). In addition to River Nile State, the States which had a relatively lower proportion of severely food insecure households included, Northern (0.4 per cent), Khartoum (0.5 per cent), White Nile (0.8 per cent), Gezira (0.9 per cent, Sinnar (1.8 per cent) and Gadarif (2.4 per cent).

The proportion of severely food insecure households was lower among those in urban areas (0.9 per cent) than among those in rural areas (4.5 per cent). The proportion of severely food insecure households was higher for female-headed households (5.0 per cent) than that for male-headed households (3.1 per cent). The proportion of severely food insecure households showed a decreasing trend with increasing level of education of the household head. The proportion of severely food insecure households was higher among households which had household head with no formal education (4.6 per cent) compared to those households whose household head had primary education (2.2 per cent) and households whose household head had secondary or higher level of education (1.0 per cent). The proportion of severely food insecure households also showed a decreasing trend with increasing level of household wealth. The proportion of severely food insecure households decreased from 7.3 per cent in the case of households in the poorest quintile to 5.9 per cent in the case of households in the second wealth quintile, to 2.4 per cent for households in the middle wealth index quintile, 0.6 per cent for households in the fourth wealth index quintile and to 0.1 per cent for households in the richest quintile.

The proportion of severely food insecure households was lower among households whose main source of income was salaries (1.6 per cent), small business (1.9 per cent), and livestock (2.4 per cent) than that for household whose main source of income was remittances (3.7 per cent), wage labour (4.1 per cent), agriculture (5.7 per cent) while the proportion was highest among households whose main source of income was firewood/charcoal (14.3 per cent).

Moderately or severely food insecure households

The proportion of households that are moderately or severely food insecure provides an indication of the proportion of population that is food insecure or vulnerable to food insecurity. The SHHS2 data indicated that a total of about 8.4 per cent of households were moderately or severely food insecure. The proportion of moderately and severely food insecure households ranged between 0.4 per cent in River Nile State and 20.1 per cent in West Darfur State.

**Figure 13.8: Moderately and severely food insecure households
Percentage of moderately and severely food insecure households, Sudan, 2010**

The SHHS2 data relating to the proportion of moderately and severely food insecure households indicate that female-headed households are more likely to be food insecure or vulnerable to food insecurity than male-headed households.

Figure 13.9: Food insecurity by gender of household head, Sudan, 2010

The SHHS2 data relating to the proportion of moderately and severely food insecure households also indicate that households in rural areas are more likely to be food insecure or vulnerable to food insecurity than households in urban areas.

Figure 13.10: Food insecurity by area of residence, Sudan, 2010

The SHHS2 data relating to the proportion of moderately and severely food insecure households also indicate that households in the poorest quintile are more likely to be food insecure or vulnerable than households in the richest quintiles.

Figure 13.11: Food insecurity by wealth index quintiles, Sudan, 2010

The SHHS2 data relating to the proportion of moderately and severely food insecure households also indicate that households which have household head with no formal education are more likely to be food insecure or vulnerable than households which have household head with primary or secondary or higher levels of education.

Figure 13.12: Food insecurity by education level of the household head, Sudan, 2010

The SHHS2 data relating to the proportion of moderately and severely food insecure households also indicate that households relying on household income sources such as salaried work, small business and sale of livestock are generally less food insecure or vulnerable to food insecurity than households who rely on household income sources such as sale of firewood and agriculture.

Figure 13.13: Food insecurity by main income source, Sudan, 2010

MATERNAL MORTALITY

Introduction

A Maternal Mortality survey was carried out alongside the SHHS2 data collection that provides the estimates of MMR by area of residence and by State. The National average of MMR was estimated at 215 per 100,000 live births. The MMR was higher in rural areas (225 per 100,000 live births) than in urban areas (194 per 100,000 live births). The MMR was lowest in Sinnar State (106 per 100,000 live births) followed by South Kordofan (112 per 100,000 live births) and the highest in South Darfur State (335 per 100,000 live births). Seven of the 15 States have MMR that is higher than the national average of 216 per 100,000 live births, a majority of them in the conflict-affected areas (Figure 10.8).

Sampling Design

The Maternal Mortality Rate was estimated using the direct method. The sample design of the MMR followed the same multi stage process with increase in the sample size that intended to extract a reliable estimate. For more information on sample design, The Government of Sudan has decided to consider the direct method for measuring Maternal Mortality Ratio, as an integral component of the SHHS. The idea of this method is to utilize the listing operation that will be undertaken to update the household list in the sample EA's as being the next to the Ultimate Sampling Unit (USU), the Household, for the purpose of collecting information on maternal deaths and live births. Nonetheless, due to the Government desire to have MMR estimates at State level with a reasonable high precision, the Sample EA's for most states greatly exceeds the requirements of the Main SHHS. In the latter case a sub sample of 40 AE's will be selected from the MMR Sample with equal probability. Again a sample of 25 HH's will be selected systematically from each of the 40 EA's. see Annex B.

In Sudan due to lack of proper civil registration systems the maternal mortality is measured through household survey and the Census conducted every 10 years, the margin of the uncertainty is such that you cannot draw firm conclusion about the direction of trend.

Maternal death is a vital event which is characterized by an extremely low prevalence level compared to other vital events. For this reason, a larger sample size is required to estimate this phenomenon with higher precision level. Yet, the cost of the field work is minimal as only two or three questions are addressed to households. In addition, data entry at household level is not needed, only at EA level.

The Government of Sudan in coordination with PAFAM Survey Project League of Arab States has decided to consider the direct method for measuring Maternal Mortality Ratio, as an integral component of the SHHS. The idea of this method was to utilize the listing operation that was undertaken to update the household list in the sample EA's as being the next to the Ultimate Sampling Unit (USU), the Household, for the purpose of collecting information on maternal deaths and live births. Nonetheless, due to the Government desire to have MMR estimates at State level with a reasonable high precision, the Sample EA's for most states greatly exceeds the requirements of the SHHS. In the latter case a sub sample of 40 AE's was to be selected from the MMR Sample with equal probability. Again a sample of 25 HH's was to be selected systematically from each of the 40 EA's.

The main advantages of the direct method are: 1- it can provide relatively recent estimates of MMR compared with the traditional sisterhood method, which usually has a reference period ranges from 5-10 years preceding the survey date; 2- With a modest added cost, the direct method can be applied to produce reasonably precise estimates for larger number of analysis domains (15 states in the situation of Sudan), In fact this cannot be done with the sisterhood method as it requires extraordinary large sample for the main survey which is unjustifiable on the ground of cost-benefit considerations; 3- the direct survey method of estimating MMR is analogous to the direct estimation method depending on vital registration data, of course if complete and reliable, thus avoiding the known technical weaknesses and limitations of the indirect sisterhood method.

Findings of MMR

Table 10.15 The SHHS2 data provides the estimates of MMR by area of residence and by State. The National average of MMR was estimated at 215 per 100,000 live births. The MMR was higher in rural areas (225 per 100,000 live births) than in urban areas (194 per 100,000 live births). The MMR was lowest in Sinnar State (106 per 100,000 live births) followed by South Kordofan (112 per 100,000 live births) and the highest in South Darfur State (335 per 100,000 live births). Seven of the 15 States have MMR that is higher than the national average of 216 per 100,000 live births, a majority of them in the conflict-affected areas (Figure 10.8).

Table 1: MMR estimates in Sudan states by residence type (urban/rural), 2010

Residence Type	MMR (100000)	Standard error	95% confidence Interval		Coefficient of variation (%)
			Lower limit	Upper Limit	
Urban	194.4	15.3	164.3	224.4	4.1
Rural	225.4	9.3	207.2	243.6	7.9
Total Sudan	215.6	8.3	199.3	231.9	3.9

Table MMR 2: MMR estimates in Sudan by state, 2010

State	MMR (100000)	Standard error	95% confidence Interval		Coefficient of variation (%)
			Lower limit	Upper Limit	
Northern	127	26.0	76.0	178.2	20.5
River Nile	147	26.7	94.8	199.5	18.1
Red Sea	280	45.2	191.5	368.6	16.1
Kassala	245	32.9	180.4	309.3	13.4
Gedariif	267	39.2	190.2	344.0	14.7
Khartoum	175	28.5	119.6	231.2	16.2
Gazira	185	24.5	137.8	233.8	13.2
White Nile	169	21.8	125.6	211.3	13.0
Sinnar	106	19.6	67.2	144.1	18.5
Blue Nile	258	22.2	214.4	301.6	8.6
North Kordofan	208	22.6	163.7	252.2	10.8
South Kordofan	112	19.1	75.0	149.8	17.0
North Darfur	178	20.5	137.3	217.8	11.6
West Darfur	322	23.5	276.2	368.3	7.3
South Darfur	335	28.9	278.1	391.7	8.6
Sudan	215.6
